Foreword

Ladies and gentlemen,

I am honored to stand before you today as the President of the XXI B-MRS Meeting and introduce this incredible gathering dedicated to the world of materials science and technology. This conference is not just an event; it is a celebration of knowledge, innovation, and the shared passion we have for advancing the field of materials science.

Our meeting reflects the profound impact that materials science has on our world. From the devices we use in our daily lives to the solutions that address global challenges, materials science is at the heart of progress.

Before we dive into the rich program that awaits us, I would like to take a moment to reflect on the importance of this gathering and the book that symbolizes our collective efforts.

This book, like our conference, is a repository of knowledge, a testament to human curiosity, and a tribute to the countless hours of research, collaboration, and dedication that each of you has invested in the field of materials science. Within these pages, you will find the latest discoveries, innovative technologies, and groundbreaking solutions that will shape the future of our discipline.

As we explore this book and the presentations throughout the conference, let us remember the essence of scientific discovery - curiosity. It is curiosity that has driven us to explore the properties of materials, to uncover the secrets of the universe at the nanoscale, and to engineer materials that have never existed before.

In our quest for innovation and sustainability, let us also embrace the idea of responsibility. Our discoveries and innovations have the power to change the world, and with that power comes the responsibility to ensure that our work benefits all of humanity and our planet. Sustainability is not an option; it is an imperative that must guide our research and our actions.

Throughout this meeting, you will have the opportunity to engage with leading experts, share your own research, and forge collaborations that will shape the future of materials science. The connections you make and the knowledge you gain here will not only advance your careers but will also contribute to the collective progress of our field.

I want to express my sincere gratitude to the organizing committee, the volunteers, our sponsors, and exhibitors for their unwavering support. Your dedication and hard work have made this event possible, and we are deeply thankful for your commitment to the advancement of materials science.

In conclusion, as we embark on this intellectual journey over the next few days, I encourage you to approach each presentation, each conversation, and each idea with an open mind and a spirit of collaboration. Let us use our knowledge and our passion for materials science to drive innovation and sustainability, and let us be stewards of the responsible use of our discoveries.

With that, I officially introduce the book of the XXI B-MRS Meeting, a testament to our collective pursuit of knowledge and progress.

Thank you, and let us embark on this exciting journey together. Enjoy the conference!

Summary

PL-Plenary Lectures

Advanced Materials for Energy Efficient Printable Electronics

Rodrigo Ferrão de Paiva Martins[1,2,3]

[1]FCT NOVA: NOVA School of Science and Technology (*CENIMAT*), [2]Centro de Investigaçãode Materiais (Lab. Associado I3N), [3]Centro de Excelência de Microelectrónica e Optoelectrónica de Processos

e-mail: rm@uninova.pt

With the growing smartness in electronic manufacturing worldwide, printed electronics capture attention because of their ability to overcome the limitation of traditional high-cost manufacturing approach which is mostly based on rigid silicon substrate. Moreover, has a great potential to offer biodegradable and recyclable solutions, by choosing low-cost substrate for printing devices, that may be recycled and/or naturally degraded in nature. This is a way forward to minimize the electronic waste (e-waste) caused by the ever-increasing number of disposable electronic devices. Relevantly, "printing electronics on paper" technology is rapidly developing in both research and electronic industry fields during the last decade. [1] For a plethora of applications, the printed devices and systems on foils require to be powered autonomously. To do so, within a sustainable approach green energy source should be exploited, such as photovoltaics thermo and mechanic energy harvester exploiting as much as possible the different materials performances as well design and architecture of the same. The development of stable, cost-effective, non-toxic, and eco-friendly printable devices for energy powering electronic printed devices on foils, such paper that are extremely lightweight, affordable, readily customizable, thin, flexible, and disposable are discussed in this presentation.

Carbon-based materials

Fernando Lázaro Freire Júnior[1]

[1]Pontifícia Universidade Católica do Rio de Janeiro (*Department of Physics*)

e-mail: lazaro@vdg.fis.puc-rio.br

The carbon nanotube was the paradigmatic material of Nanoscience and Nanotechnology in the nineties. Despite the huge expectations created by its potential applications, few were confirmed. A similar expectation was experienced with studies on graphene, including the replacement of silicon in nanodevices, which is far from being a reality. However, the study of the properties of nanotubes and graphene has brought spectacular results from the pointof view of basic research, which explains the large number of groups dedicated to these subjects. Today, research on low-dimensional materials is diversified including, among others, TMDs, silicenes, phosphorenes, etc. this seminar, I will present a review of our research activity focused on carbon-based materials, starting with diamond-like carbon films, targeting applications such as protective coatings, passing through nanotubes, graphene, and quantum dots, with applications in sensors.

Computational Modeling and Design of OLED Emitters Based on Earth-Abundant Elements

Christel M. Marian[1]

[1]Heinrich Heine Universität Düsseldorf (*Institute of Theoretical and Computational Chemistry*)

e-mail: Christel.Marian@hhu.de

To achieve 100% internal quantum efficiency in electroluminescent devices, all singlet and triplet excitons must be harvested. The design of novel OLED emitters therefore requires detailed knowledge about excited-state decay pathways and transition probabilities including singlet-triplet interconversion processes. Quantum chemical methods can provide information about the properties of electronically excited states and their couplings and thus aid in understanding the underlying mechanisms. In our group, the DFT/MRCI method, a density functional theory based multireference configuration approach, and the associated property programs SPOCK, DELTA and VIBES are employed for this purpose. As the talk will show, these methods have proven to be well suited for evaluating spectra as well as intersystem crossing (ISC), internal conversion (IC) and radiative rate constants required for modeling the excited-state decay pathways of OLED emitters.

In search for bright and operationally stable electroluminescent emitters, the focus recently shifted from the well-established phosphorescent Ir^{III} and Pt^{II} emitters to Cu^{I} coordination compounds and metal-free donor-acceptor systems based on thermally activated delayed fluorescence (TADF). Cu is much more earth abundant than Ir or Pt and hence much less expensive. Moreover, due to the filled 3d shell, dissociative metal-centered (MC) d-d* excited states are energetically not low-lying in Cu^{I} complexes. Our computational studies suggest that linear and three-coordinated Cu^{I} carbene complexes with low-lying ligand-to-ligand charge transfer (LLCT) triplet states typically emit TADF whereas complexes with T_1 states of metal-to-ligand charge transfer (MLCT) character are phosphorescent.

Like Cu^{I}, Zn^{II} possesses a d^{10} configuration in the electronic ground state. Zn complexes might therefore qualify as TADF emitters as well. The low-lying states of newly designed Zn^{II} carbene dithiolates have predominantly LLCT character. In conjunction with non-negligible spin-orbit coupling (SOC) due to participation of sulfur orbitals in the electronic excitation, the small singlet-triplet energy gap ΔE_{S-T} leads to efficient triplet-to-singlet up-conversion.

TADF in metal-free organic through-bond and through-space charge-transfer (CT) systems often follows a different mechanism. These compounds have small ΔE_{S-T} values as well, but the mutual SOC of their S_1 and T_1 states is tiny. Spin-vibronic interactions with energetically close-by local excitations are found to essential for promoting the reverse ISC in metal-free compounds.

Graphene and Related Materials: From Production to Applications

Andrea C. Ferrari[1]

[1]University of Cambridge

e-mail: acf26@cam.ac.uk

Disruptive technologies are usually characterised by universal, versatile applications, which change many aspects of our life simultaneously, penetrating every corner of our existence. In order to become disruptive, a new technology needs to offer not incremental, but dramatic, orders of magnitude improvements. Moreover, the more universal the technology, the better chances it has for broad base success. Significant progress has been made in taking graphene and related layered materials from a state of raw potential to a point where they can revolutionize multiple industries. I will overview the progress done thus far and the future roadmap.

Innovations in Materials and Technologies to Face New Threats in Water Treatment

Conchi O Ania[1]

[1]Centre national de la recherche scientifique (*CEMHTI*)

e-mail: conchi.ania@cnrs-orleans.fr

Providing fresh water in a sustainable and affordable manner is one of the greatest global challenges of our society, where over 2 billion people suffer from water scarcity. These estimations are projected to continuously increase owing to the growth of population, water pollution, climate change, and yet the impacts of COVID-19 pandemic. Despite the maturity of many technologies to assure water availability (providing fresh water and depollution used wastewater), these are mostly based on energy-intensive processes integrated in large and centralized infrastructures that are inaccessible to off-grid communities. Therefore, current challenges in water treatment are linked to the need for developing effective solutions to face emerging pollutants, capable of assuring a feasible economic upgrade of existing plants.

Conventional biological treatments are assisted with tertiary processes such as adsorption to improve the efficiency of the treatments. However, the cost associated to the regeneration of the spent adsorbents still represents a major limitation for massive implementation. On the other hand, advanced oxidation processes have become an interesting alternative for the simultaneous removal and degradation of pollutants. However, innovations on new materials based on sustainable approaches that can be integrated into physical, chemical, and biological processes to treat all types of waters are needed and require global research efforts.

This lecture will focus on the application of advanced adsorption, electrochemical and photocatalytic oxidation processes based on porous carbons, semiconductors and their hybrids combined with processes based on renewable energies for the removal and/or degradation of emerging pollutants in water. Examples will cover our research activities at lab-scale, as well as various case studies at pilot scale on the application of these technologies and materials to wastewater from industrial and treatment plant facilities origins.

These research activities have received funding from the European Union’s Horizon 2020 research and innovation program under the grant agreement № 776816 (Project Ô), the European Research Council (grant 648161, PHOROSOL) and Région Centre Val de Loire (grants MOSAIK, PRESERVE, MATHYFON).

Luminescent nanothermometers in biomedicine: past, present and future

Daniel Jaque[1]

[1]Universidad Autónoma de Madrid (*Fisica de Materiales*)

e-mail: daniel.jaque@uam.es

Temperature is crucial in cell and tissue dynamics. Because of that, temperature has emerged as a physiological parameter that can be potentially used for advanced diagnosis and treatment of different diseases ranging for cardiovascular misfunctions to alterations in the nervous system. Such advances require the development of new methods capable of remote thermal sensing in biosystems (from individual cells to organs and tissues). Unfortunately, conventional methods such as classical thermometers of thermographic cameras fail to provide such thermal readouts.

A luminescent nanothermometer (LNTh) is defined as a luminescent nanoparticle whose luminescence properties are strongly temperature dependent. In this case, remote thermal reading just requires an adequate analysis of the luminescence. LNThs have been applied in different fields ranging from microelectronics to nanofluids. But it is in the field of biomedicine where LNThs have resulted of most relevance. As I will summarize in this talk, LNTHs have been demonstrate capable of accurate thermal sensing in individual single cells, of in vivo early diagnosis of tumor development and of providing control to in vivo thermal treatments. I will include a critical analysis of the future of the field, the challenges that LNThs are facing and the actual possibility of transferring luminescent nanothermometry to the clinical world.

Porous nanomaterials for capturing, sensing andreleasing

Luisa De Cola[1]

[1]Istituto di Richerche Farmacologiche Mario Negri（*Biochemistry*）

e-mail: luisa.decola@unimi.it

Design and realization of materials able to be biocompatible, degradable and programmed to target only desired organs and/or cells is a major challenge that involve several disciplines. We have for several years focused on organosilica nanoparticles able to break once they are internalized in cells and showed that it is possible to change morphology, and porosity. Very recently we have shown that cage type structure of small dimension (20 nm) can escape macrophage filtering [1] and reach the tumor site. Such findings have been tested to study the therapeutic effect of such nanocarriers for fighting the malignant pleural mesotelioma. In vivo data showed an interesting 50% reduction of tumor growth when mice were treated with a Pt(IV) prodrug, entrapped in the nanocages, at an equivalent dose of the free platinum complex [2]. However silica nanoparticles are also able to become responsive to biological input when synthetic nucleic acids and analogs as constitutive components of the organosilica structures [3]. The system can be programmed to be more dynamic and responsive by designing supramolecular organo-silica systems based on PNA- derivatives that can self-assemble through direct base paring or can be joined through a bridging functional nucleic acid, such as the ATP-binding aptamer [4]. Finally the capture of small metabolites such as the neurotransmitters serotonin and dopamine with unprecedented affinity and selectivity even in saline biofluids, is discussed using microporous hybrid materials. In particular zeolite-based artificial receptors which capture the analytes have been engineered with fluorescent reporters and results in biofluids are illustrated [5].

I wish to thank the European Union’s Horizon 2020 research and innovation programme (grant agreement No 964386 - FET Open Mimic-Key project).

A-Artificial intelligence applied to materials science

Combining the Power of High-Throughput ab initio Calculations and Machine Learning towards Materials Informatics

Gian-Marco Rignanese[1]

[1]Université Catholique de Louvain (*IMCN*)

e-mail: gian-marco.rignanese@uclouvain.be

The progress in first-principles simulation codes and supercomputing capabilities have given birth to the so-called high-throughput (HT) ab initio approach, thus allowing for the identification of many new compounds for a variety of applications (e.g. lithium battery and photovoltaic). As a result, a number of databases have also become available online, providing access to various properties of materials, mainly ground-state though. Indeed, for more complex properties (e.g., linear or higher-order responses), the HT approach is still out of reach because of the required CPU time. To overcome this limitation, machine learning approaches have recently attracted much attention in the framework of materials design.

In this talk, I will review recent progress in the emerging field of materials informatics. I will briefly introduce the OPTIMADE API [1] that was developed for searching the leading materials databases (such as AFLOW, the Materials Cloud, the Materials Project, NOMAD, OQMD, ...) using the same queries. I will introduce the MODNet framework and its recent developments for predicting materials properties [2-3]. This approach, which is particularly well suited for limited datasets, relies on a feedforward neural network and the selection of physically meaningful features. Finally, I will illustrate the power of materials informatics, combining high-throughput ab initio calculations and machine learning, through a few recent examples.

Engineering Soft-Matter with Agent-Driven High-Throughput Experiments

Lilo D. Pozzo[1], Kiran Vaddi[1], Karen Li[1], Fábio Baum[1], Huat Thart-Chiang[1], Maria Politi[1]

[1]University of Washington (*Chemical Engineering*)

e-mail: dpozzo@uw.edu

Artificial intelligence (AI), when paired with laboratory automation, can greatly accelerate materials optimization and scientific discovery. For example, it can be used to efficiently map a phase-diagram with intelligent sampling along phase boundaries, or in 'retrosynthesis' problems where a material with a target structure is desired but a synthetic route is not known. These approaches are especially promising in soft matter and polymer physics, where design parameters (e.g. chemical composition, MW, topology, processing) are vast and where properties and function are intimately tied to molecular design features. However, for AI algorithms to operate efficiently in these spaces, they must also be 'encoded' with relevant domain expertise specific to the problems being tackled. This talk will cover recent advances in hardware and software tools for accelerated materials optimization for polymers and soft matter systems. Finally, it will outline remaining challenges in practical implementations and identify future opportunities for research.

Graph recommender system for ionic substitution: Discovering new materials

Gustavo Dalpian[1,2]

[1]Universidade Federal do ABC, [2]Instituto de Física/USP

e-mail: dalpian@gmail.com

Traditional chemical heuristics have been very important for discovering new inorganic compounds in the past, but as they are usually based on patterns observed on a limited or specific set of materials, they are not generalizable as once thought. Today, as one can access the data of hundreds of thousands of inorganic materials present in databases, it has become frequent that many Material Science projects have become data-driven, i.e., they use large amounts of materials data and statistical methods, such as Machine Learning(ML), to uncover new patterns and explore the phase space of compounds. In the ML context, recommender systems are widely used in various scientific and nonscientific fields. For instance, in the e-commerce area, these systems recommend users new products by analyzing their past purchased products or by collaborative filtering: a system where a heterogeneous network/graph composed of users and items and their interactions is used as input to recommend new products to users. By using this same principle framework and OQMD''s materials database, we were able to build an analogous graph with the elements in the periodic table together with the set of all described crystal structures'' sites as two classes of entities. The relationships between the two classes are given by the occupancy ofa site by an element and it is weighted by the compound''s thermodynamic stability. The heterogeneous graph is used to build an embedding space with a vector representation for each entity (elements and sites). These vector representations were then used as input to model a recommender system. In addition to finding new materials by uncovering new element-site occupancies, we were also able to analyze the embedding space and find interesting patterns in chemical similarities between elements and the local geometry of sites. We thank financial support from FAPESP and from the Materials Informatics INCT (CNPq).

Machine learning and Natural Language Processing in Materials Sciences

Osvaldo Novais de Oliveira Junior[1]

[1]Universidade de São Paulo

e-mail: chu@ifsc.usp.br

The advent of large language models, as those used in tools such as ChatGPT, is bound to transform the way the scientific literature is mined and how knowledge discovery will be done in the future. While this applies to all scientific areas, specific tools for materials sciences are already available, which are capable of providing unprecedented results in terms of the identification of materials and their application. In this lecture, a discussion will be made of data analytics approaches, including natural language processing capabilities with deep learning, which can be implemented according to a pipeline of tools combining information visualization and complex networks. With the latter networks, one may probe the landscape of research areas, where papers from a given topic can be clustered into communities whose characteristics can be analyzed in detail. Also to be discussed is the possibility of leveraging multimodal data from distinct sources to produce surveys of the literature, and develop monitoring systems for diagnostics and surveillance. An example will be shown of the use of machine learning to process sensing data and clinical information for diagnosis.

A machine learning-enhancement for portable electrochemical detection of viruses.

Ronaldo Valentin Challhua Reynoso[1], Ronaldo Cristiano Prati[1], Ana Champi[1]

[1]Universidade Federal do ABC

e-mail: ronaldo.challhua@ufabc.edu.br

Biosensors are small analytical devices which converts a biological response into a quantifiable and processable signal. Among the different methods available in biosensing, electrochemical detection presents several advantages such as high sensitivity, easy-of-operation, cost-effectiveness and miniaturization capability. The current study proposed innovative machine learning-enhanced electrochemical detection of enveloped viruses such as rabies virus (RABV) and SARS-CoV-2. Portable detection was achieved by using an LMP91000 IC portable potentiostat circuit and a microfluidic sensor. Data were collected in collaboration with Campus Fiocruz the Atlantic Forest - RJ and Pasteur Institute - SP. Voltammetry results for rabies detection were used in data-mining process, feature extraction was performed using electrochemical parameters to build a dataset with uncovering patterns and other valuable information. Several statistical analysis and visualization technique were conducted to evaluate the constructed electrochemical dataset. Correlation-based algorithms, recursive feature elimination and feature importance were used for feature selection and evaluated by SHapley Additive exPlanations (SHAP) values. We experimented with several ML classifiers, namely support vector machine (SVM), Gaussian Naive Bayes (GNB), multi-layer perceptron (MLP), k-nearest neighbors (KNN), logistic regression (LR) and ensembled methods, and evaluate our findings in terms of different evaluation metrics such as recall and precision. Our analysis showed the best score of metrics for k-NN classifier for diagnostic tasks for rabies virus. The trained model will be implemented on ATmega328 microcontroller with embedded programming. Our study shows the potential of ML models in the field of electrochemical biosensor development with focus on parameter extraction and selection based on electroanalytical analysis, which can be extended to develop new tools for disease diagnosis in the future.

First principles physics-informed neural network for quantum wavefunctions and eigenvalue surfaces

Gabriel Ravanhani Schleder[1], Marios Mattheakis[2], Daniel T. Larson[2], Efthimios Kaxiras[2]

[1]Brazilian Nanotechnology National Laboratory, [2]Harvard University

e-mail: gabriel.schleder@lnnano.cnpem.br

Physics-informed neural networks have been widely applied to learn general parametric solutions of differential equations. Here, we propose a neural network to discover parametric eigenvalue and eigenfunction surfaces of quantum systems. We apply our method to solve the hydrogen molecular ion. This is an ***ab initio*** deep learning method that solves the Schrödinger equation with the Coulomb potential yielding realistic wavefunctions that include a cusp at the ion positions. The neural solutions are continuous and differentiable functions of the interatomic distance and their derivatives are analytically calculated by applying automatic differentiation. Such a parametric and analytical form of the solutions is useful for further calculations such as the determination of force fields. Acknowledgement Fapesp process 17/18139-6

Machine learning as a tool on multiscale materials modelling: building bridges over scales

Caetano Rodrigues Miranda[1]

[1]Instituto de Física da Universidade de São Paulo (*DFMT*)

e-mail: crmiranda@usp.br

Recently, computational materials modelling has been successfully used to understand the fundamental mechanisms underlying materials phenomena and processes. Strategies based on computational-guided experiments allow us to optimise and design materials (composition, morphology and processes). Important achievements in the discovery and design of materials through multiscale molecular simulations have been accomplished in our group, coupling first-principles calculations, molecular dynamics and lattice Boltzmann methods (1-4). However, a hierarchical multiscale approach represents a considerable challenge in modelling physical phenomena ranging from molecular to micro to macro scales. A key issue is that physical-chemistry phenomena in materials can occur on different scales. Here, we will share our strategies to incorporate machine learning methods to bridge scales over multiscale materials modelling. The case studies range from i) screening of catalyst and, ii) the development of interatomic potential energies based on First Principles Calculations and Molecular Dynamics, iii) fluid-fluid interfaces at the atomic scale, and iv) the prediction of pressure and velocity fields on mesoporous simulations usingLattice Boltzmann methods. The applications range from the CO2 mineralisation processesof CO2 and CO2 reduction towards value-added products and fluid flow through porous media. A bonus is using machine learning-based models coupled with virtual reality tools towards an interactive materials design on the fly.

Machine Learning-Assisted Exploration of 111-Type 2D Perovskite Structures for Photovoltaic and Optoelectronic Applications: A High-Throughput Screening Approach

Rogério Almeida Gouvêa[1], Pierre-Paul De Breuck[2], Gian-Marco Rignanese[3], Marcos Jose Leite Santos[1]

[1]Universidade Federal do Rio Grande do Sul (*PGCIMAT - Programa de pós-graduacão em ciência dos materiais*) , [2]Université Catholique de Louvain, [3]Université Catholique de Louvain (*IMCN*)

e-mail: rogeriog.em@gmail.com

In this study, we harnessed machine learning to scrutinize approximately 10 million 111-type 2D perovskite structures with the formula $A_3B_2X_9$for photovoltaic and optoelectronic applications. We examined six A-site cations, 23 B-site cations, and five anions, adhering to the stoichiometry $A_{6-2x}A^2{}_{2x}B_{4-y}B^2{}_yX_{18-3z}X^2{}_z$and confining compositions to halides.We applied the M3GNet graph neural network to ascertain optimal configurations for each composition, resulting in 1.8 million unique, lower-energy compositions. Subsequently, we trained a Materials of Optimal Descriptor Network (MODNet) model on 1.5 million materials from the Open Quantum Materials Database (OQMD) to predict stability based on compositions, eliminating those with a convex hull distance exceeding 0.2 eV/atom. This process yielded approximately 100,000 potential stable compositions.To further refine our selection, we utilized an ensemble of MODNet models trained on the entire OQMD database and exclusively on halides for formation energy and band gap calculations. This method enabled the identification of promising candidates with low band gaps and enhanced stability, ideal for photovoltaic and optoelectronic applications. Our approach showcases the remarkable capabilities of advanced machine learning techniques in delving into extensive chemical spaces that are impractical for expensive ab-initio calculations and exceedingly challenging for experimental synthesis. This methodology has the potential to significantly expedite the discovery and design of novel materials in the photovoltaic and optoelectronic domains contributing to advancements in perovskite materials research and fostering progress in renewable energy technologies. Furthermore, this approach can be tailored to address a wide range of research challenges in the broader field of materials science.

Machine learning-assisted MD simulation of melting in superheated AlCu crystal validates the Classical Nucleation Theory

Azat Tipeev[1], Roman E. Ryltsev[2,3], Shiddhartha Ramprakash[4], Nikolay M. Chtchelkatchev[5], Edgar Dutra Zanotto[1]

[1]Federal University of Sao Carlos (*Department of Materials Engineering*), [2]Institute of Metallurgy, Ural Branch of the Russian Academy of Sciences, 620016 Ekaterinburg, Russia, [3]Ural Federal University, 620002 Ekaterinburg, Russia, [4]National Institute of Technology Tiruchirappalli, 620015 Tamil Nadu, India, [5]Vereshchagin Institute for High Pressure Physics, Russian Academy of Sciences, 108840 Troitsk, Moscow, Russia

e-mail: azattipeev@gmail.com

We performed comprehensive molecular dynamics (MD) simulations of spontaneous melting of a superheated AlCu crystal under atmospheric pressure at five temperatures, covering a range of T/T_L=1.1-1.3, where T_L is the liquidus temperature. Two realistic AlCu models were investigated: one described by the modified embedded atom method (MEAM) and the other by an interatomic potential generated by an artificial neural network machine learning (ML) approach, extensively trained on a massive *ab initio* dataset of liquid and crystal configurations. The temperature dependencies of the mean nucleation time, nucleation rate, critical nucleus size, work of formation, and nuclei growth rate were determined by MD simulations. Using these simulation-generated data, the theoretical nucleation rates were calculated by the Classical Nucleation Theory (CNT) with no fitting parameters. We found excellent agreement between the theoretically and MD-computed liquid nucleation rates for both MEAM and ML crystals. Notably, the computational value of the effective solid-liquid interfacial free energy aligns with its recent experimental measure. Moreover, the CNT qualitatively and quantitatively described the underlying details of liquid nucleation in our ML solid, accurately reproducing the kinetic factor and the size, formation energy, and growth rate of the critical nuclei. Thus, the melting of the AlCu model created through ML-processed quantum calculations, that is, not relying on hand-crafted interatomic potential functions, was successfully described by the CNT phenomenological formalism, without any adjustable parameters.

Natural language processing towards a data-oriented design approach for producing biochar and hydrochar

Amauri Jardim Paula[1,2]

[1]Universidade Federal do Ceará (*Física*) , [2]Ilum Escola de Ciências

e-mail: amaurijp@gmail.com

To effectively apply biochar and hydrochar in various technologies that can enhance human life, it is crucial to comprehend their properties and characteristics, as they significantly impact their application. Understanding the correlations between experimental conditions and the resulting properties of these carbon-based materials can provide a better control of the synthesis process and final product properties. This could ultimately lead to a controllable design of biochar and hydrochar for use as CO2 adsorbents, soil amendments, and in other applications. Here we describe how natural language processing (NLP) can be used to extract relevant data from thousands of peer-reviewed scientific papers describing the synthesis conditions and properties of biochar and hydrochar. With the collected data, machine learning (ML) algorithms could be employed to identify previously unknown correlations between synthesis and properties, such as: (i) how the carbonization temperature can influence the material final surface area (SA); (ii) which are the most suitable biomass precursor to produce biochar and hydrochar with the largest adsorbent capacity; and (iii) what processing steps must be performed to achieved a high C/H ratio. By adopting data-driven and statistically supported approaches, we show that there is a great potential to change traditional manufacturing paradigms and accelerate informed decision-making on the design of carbon-based materials, especially those produced from renewable sources.

Prediction of self-healing properties of concretemodified with fibers and bacteria

Carolina Luiza Emereciana Pessoa[1], Victor Hugo Peres Silva[1], Ricardo Stefani[2]

[1]Universidade Federal de Mato Grosso (*Programa de Pós-Graduação em Ciência de Materiais*) ,
[2]Universidade Federal de Mato Grosso

e-mail: carolinaepessoa@gmail.com

Self-healing concrete has been studied for decades as an alternative material to overcome problems such as cracks and low durability of conventional concrete. However, laboratory experiments can be costly and time-consuming. Thus, predictive computational models that can estimate the properties of cementitious materials are being increasingly applied to investigate and develop new types of concrete. In this work, Machine Learning (ML) models were developed to predict and analyze the repairing rate of the cracked area and capillary water absorption in concrete modified with alkali-resistant bacteria, polyvinyl alcohol (PVA) and polypropylene fibers (PP). The empirical datasets used for training the models were produced and published by Feng et al [1] and Su et al [2]. The implemented ML algorithms were Simple Linear Regression (LR), Multiple Linear Regression (MLR), Support Vector Machine (SVM) and Random Forest Regressor (RFG). The results show that among the algorithms, the most efficient and accurate were the SVM and the RFG. In addition, the model trained with the dataset containing the variables related to the rate of the cracked area obtained better prediction performance. RFG was more efficient and accurate in predicting the cracked area rate (R2 = 0.98, RSME = 0.0009), followed by SVM (R2 = 0.95, RSME = 0.0028), while for predicting water absorption, SVM showed better performance (R2 = 0.76, RSME = 0.0566), followed by the RFG (R2 = 0.71, RSME = 0.0651). Thus, the results show that ML can be a valuable tool for the AI and Data-Driven development of new and improved concrete.

Supervised machine learning models developed topredict the properties of biocompatible Ti alloys

Vinicius Richieri Manso Gonçalves[1], Luiz Paulo Lopes Fávero[2]

[1]Universidade Estadual Paulista (*School of Science*) , [2]Universidade de São Paulo (*Faculdade de Economia, Administração e Contabilidade (FEA)*)

e-mail: viniciusmanso@gmail.com

Titanium (Ti) and its alloys are considered suitable metallic materials for biomedical applications, mainly for bone implants. Beyond good combination of properties that attend different biocompatibility requirements, Ti alloys can achieve values of elastic modulus which approach the values presented by human bone [1]. However, due to the variability in the properties achieved with the addition of different chemical elements, Ti alloys continue to be studied for searching the chemical composition which results in the lowest elastic modulus. In this way, with the availability of reliable database in the scientific literature for different chemical compositions of Ti alloys already experimentally characterized, as well as, with the recent published architectures of promising artificial neural network (ANN) models [2], three new models of ANN were created in the present work aiming to aid the development of new Ti alloys for biomedical application. Thus, the weight percentages of Mo, Nb, Ta, Zr and Sn were considered as input neurons, while the elastic modulus was considered as output neuron. Different activation functions were applied to the neurons in the hidden layers, in addition to different standardizations performed on the data before modeling. The results showed that the model with the Sigmoid function and with the standardization between zero and one achieved good convergence, registering the root mean squared error equal to 10.3 GPa, even with few epochs in the training. Therefore, ANN modeling showed promise for greater use in the design of new Ti alloys.

Synthesizing double halide perovskites with machine learning prediction

Tatiane Pretto[1], Fábio Baum[2], Marcos Jose Leite Santos[3]

[1]Universidade Federal do Rio Grande do Sul (*Instituto de Química*) , [2]University of Washington (*Chemical Engineering*) , [3]Universidade Federal do Rio Grande do Sul (*PGCIMAT - Programa de pós-graduacão em ciência dos materiais*)

e-mail: tatianepretto@gmail.com

Lead perovskite solar cells have been successful in achieving an efficiency of over 25% in just over a decade of research. Once the lead perovskites instability remains a challenge, there has been a growing interest in more stable lead-free perovskites, such as double halide perovskites. [1] However, the synthesis process is complex due to the numerous compositions and conditions involved. To improve this search, a multi-target machine learning study was conducted to analyze previous experimental data and predict synthesis parameters. The predictions were used to synthesize two new double halide perovskites (Cs2CuLaCl6 and Cs2AgLaCl6) by the hot injection method. We created a database to describe the synthesis and properties of the perovskites, which had 10 features and 164 observations after cleaning and filtering. Three algorithms that support the multi-target approach were applied: decision trees, random forest, and neural networks. The five outputs used to train the algorithms and predict conditions included reagent quantities, time of reaction, and bandgap. We chose random forest as the final model and synthesized the perovskites, by the hot injection method, based on its predictions. By the precipitate XRD diffraction patterns, we observed the formation of cesium chloride. On the UV-Vis spectra of the Cs2CuLaCl6 and Cs2AgLaCl6 supernatants, the indirect bandgaps were 3.5 and 3.4 eV, respectively. These values are close to the predicted bandgaps of the perovskites by the machine learning model: 3.8 and 3.7 eV, respectively. The direct bandgaps (2.7 and 2.9 eV) may indicate possible intermediate formations. We must carry out further characterizations to confirm the formation of the perovskites. Future research will focus on optimizing the synthesis process and testing the materials in solar cells to evaluate their device performance.

e-mail: giliandro.farias@hotmail.com

The conversion of CO2 into valuable fuels and chemicals has drawn significant attention due to the possibility of tuning the fuel yield and selectivity by changing the catalyst. Regarding this, decades of advances in theoretical and experimental methods have produced a compendium of complex data containing valuable information on materials that can and should be used to optimize reactions. In this work, our approach combines machine learning methods and DFT data to screen catalysts and find the best candidate to use as a catalyst to CO2 conversion. As previously reported, the C-C bond formation is the determinant step to obtain C2+ products of higher commercial interest, such as ethanol. The C-C bond coupling is usually related to intermediates, such as C* and CO*. The elemental reactions from gaseous CO2 to these intermediates and side reactions can be used to find the most favorable reaction pathway. The side reactions can lead to usually undesired products such as methane and methanol. As theoretical information from each elemental reaction can be found in the literature for many catalysts, it can be used to feed a dataset and train a machine-learning algorithm. We are also performing DFT calculations to improve the dataset, considering catalysts that already showed good experimental results, mixtures of metals and single-atom supported by usual substrates. The selected catalysts will be both theoretically and experimentally verified. As the solvent and the alkaline metals cations were previously demonstrated to play an essential role in these reaction pathways, they will also be considered.

Artificial neural networks applied in the catalytic process of urease and conjugated polymer thin films

Cléber Gomes de Jesus[1], Rebeca da Rocha Rodrigues[2], Carlos Alexandre Moreira da Silva[3],
Laura Oliveira Péres[2]

[1]Universidade Federal de São Paulo (*Departamento de Química*) , [2]Universidade Federal deSão Paulo (*Química*) , [3]Universidade Federal de São Paulo (*Departamento de Engenharia Química*)

e-mail: cjesus11@unifesp.br

The increasing demand for molecule detection and quantification leads to the study and development of several techniques in biosensor production. The production of these devices is essential to have a model that can unravel and facilitate interpreting the obtained data. However, catalytic processes generally involve several variables, creating a non-linear system that conventional methods may not model [1]. Therefore, Artificial Neural Networks (ANNs) have claimed attention due to their capability to model data from several sources, even non-linear ones, by mimicking the human brain's learning process. In summary, the present work tries to integrate experimental data and simulations using ANNs. The catalytic films were made by the adsorption of urease in conjugated polymers using the spin coating technique, and the catalytic activity was obtained by an in-situ reaction, as described in the literature [2]. In the model development, the multilayer perceptron ANN was used since 12 architectures were created varying the variable disposition, and 45 structures were created for each architecture varying the number of neurons, algorithms of optimization, and transfer function. As a result, the best structure performed the testing step with a Pearson's correlation coefficient (ρ) of 0.9980 and objective function in the order of 10-5. Simulations were performed with new data to evaluate the efficiency of the trained ANN. The results achieved a mean absolute percentage error below 4% with good reproducibility of the experimental data.

Boosting MODNet Capabilities: Fast Featurization, Gradient Boosting Augmentation, and Pretrained Model Synergy for Materials Science Predictions

Rogério Almeida Gouvêa[1], Pierre-Paul De Breuck[2], Gian-Marco Rignanese[3], Marcos Jose Leite Santos[1]

[1]Universidade Federal do Rio Grande do Sul (*PGCIMAT - Programa de pós-graduacão em ciência dos materiais*) , [2]Université Catholique de Louvain, [3]Université Catholique de Louvain (*IMCN*)

e-mail: rogeriog.em@gmail.com

Machine learning models, particularly feature-based and graph neural network models, have propelled materials science by expediting new material discovery and property optimization. MODNet (Material Optimal Descriptor Network) is a versatile feature-based framework adept at predicting a wide range of crystal properties. It utilizes a feedforward neural network and physically meaningful features, selected by an efficient relevance-redundancy algorithm. Benchmarking against the MatBench v0.1 test suite showcases MODNet''s effectiveness, particularly with smaller datasets. MODNetFast, a featurizer developed in this work, addresses the slow featurization issue in MODNet, which relies on MatMiner featurizers. It adopts an efficient featurization process using autoencoders and MEGNet models to compress and reproduce essential features. Additional features, such as OrbitalFieldMatrix and pretrained MEGNet model dense layers, are integrated to improve prediction accuracy and generalization. Consequently, this new featurizer reconciles the benefits of feature-based models, boosted by graph-based models'' accuracy, while accommodating larger datasets. Simultaneously, a gradient boosting augmentation technique has been implemented in MODNet. XGBoost models are trained on optimal features across the entire training data and subsets based on similarity to generate additional predictors. Although this method is prone to overfitting, it enhances predictions in several cases and is employed only when it reduces validation loss compared to the original model. In conclusion, MODNetFast effectively extends MODNet''s applicability to larger datasets and leverages information from pretrained models and complex features. Furthermore, the gradient boosting augmentation approach refines MODNet''s performance in specific cases, making the combined framework a valuable expansion of MODNet''s capabilities.

[1]Instituto de Física da Universidade de São Paulo (*Departamento de Física dos Materiais e Mecânica*), [2]Universidade Federal de Minas Gerais (*Departamento de Física*), [3]Instituto de Física da Universidade de São Paulo (*DFMT*)

e-mail: alvaro.torrez@usp.br

The chemical reduction of carbon dioxide (CO2), a primary contributor to global climate change, is a necessary process that has been studied extensively. There are proposals to transform CO2 into chemical products through catalytic routes. The goal is to convert this gas into value-added products, e. g., oxalate salts, oxalic acid, hydrocarbons and methanol, using metallic catalyst and metallic heterostructures. In these processes, many intermediate products can arise. The interaction between the adsorbates and surface influences the selectivity, and it would be possible to control the final products by controlling the adsorbability of chemical species. Thus, understanding the behavior of catalysts is fundamental to optimizing and controlling the reduction process. In this work, we used machine learning methods to predict the adsorption energies of different chemical species related to CO2 reduction on different catalysts. We implemented machine learning models using the database''s information of public repositories and useful libraries to represent the interaction between the adsorbate and the catalyst. Our results showed the robustness of machine learning models and the ability of these methods to speed up the screening materials to specific goals at a low computational cost [1]. We emphasize the capability of our model to predict the adsorption energy of ions on metallic surfaces. It has a special significance due to the difficulty of calculating the correct energy for charged systems by traditional atomistic simulations.

Machine Learning prediction of Self-Healing Capacityof Concrete with the use of Synthetic Data

Ricardo Stefani[1], Franciana Sokoloski[1]

[1]Universidade Federal de Mato Grosso (*Campus Araguaia*)

e-mail: rstefani@ufmt.br

Concrete is the most widely used material in civil engineering. It is inexpensive, durable and resistant. Although its advantages, concrete has also some disadvantages, such as cracking, which cause high permeability in concrete structures. Thus, life span of concrete is reduced as cracking increases. Therefore, there is a concern about fixing cracks before they comprise the concrete or even the entire building. Although crack fixing is often made by adding new cementitious materials over the cracks, self-healing concrete has been subjected to research for years, including self-healing in concrete aided by bacteria. Machine learning (ML) can assist the prediction and development of new concrete formulae enriched with bacteria. Moreover, ML can reduce the time and cost in the development of new self-healing concrete. In this work, ML models to predict the capacity of bacteria-rich self-healing concrete were developed. Data of bacterial self-healing concrete were collected from the literature. A total of 38 occurrences involving six bacteria were collected from the literature. All data were record into a CSV table. As machine learning algorithms often requires large amount of data [2], the data compiled from the literature were subjected as a source to synthetic data generation via the Synthetic Data Vault. After data generation, two ML models algorithms: Support Vector Machines (SVM) and K-nearest neighbor (KNN) were trained using repeated cross-validation to predict if each concrete formula would have self-healing capacity. SVM models were able to predict self-healing with an accuracy of 0.913 and KNN with an accuracy of 0.875. Therefore, we conclude that SVM and KNN can be further improved to predict self-healing capacity of concrete with high accuracy.

Using Neighborhood Cultivation Genetic Algorithm to Identify the Parameters of a Time Dependent Mechanical Model for PTFE Powder Pressing.

Vinicius Sciuti[1], Lucas A. Fernandes[2], Matheus Furlan[2], Salvino M. Macêdo[2], Rodrigo Bresciani Canto[1]

[1]Universidade Federal de São Carlos (*DEMa*) , [2]Programa de pós-graduação em Ciência e Engenharia de Materiais

e-mail: vinicius.sciuti@ufscar.br

Material Science is the study of the structure, properties and processing of materials. The use of Artificial Intelligence (AI), represented by the Neighborhood Cultivation Genetic Algorithm (NCGA) can reduce the number of tests demanded to identify complex mechanical behavior parameters. As an example, the uniaxial pressing of Polytetrafluoroethylene (PTFE) pellets may show time-dependent properties due to the rearrange of them, resulting in creeping and stress relief. It demands a numerical model capable of time-dependent representation of mechanical properties. PTFE is commonly used in applications when high working temperatures (up to 260 °C) and chemical stability are needed. The main disadvantages of PTFE in the industry are the costs associated with the manufacturing process and raw material production. In the melting state, PTFE presents a very high viscosity that requires a processing route based on pressing of the pellets followed by sintering. The identification of models and calibration of the parameters are very important for the numerical simulation of the process, and demands many experimental tests. However, this number may be reduced by using an AI algorithm as NCGA. In this work, uniaxial pressing tests were carried out in a close die. A max displacement was set for the piston, which velocity varied in each test (40, 4, 0.4 e 0.04 mm min-1). After pressing, a dwell time was used to observe stress relief effects. The experiments were modeled in AbaqusTM using Drucker-Prager/Cap (DPC) and the viscoplasticity model of Singh-Mitchell. To identify the viscoplastic parameters, the computational results were compared to the experimental ones and the Singh-Mitchell parameters were varied by the NCGA until achieve a good correspondence between results. This methodology reduced the number of experiments, in real and virtual world, and helped to the set-up of experimental variables. Acknowledgment FAPESP grant # 2021/14452-7.

B-Design of intelligent hybrid and composite nanosystems: from Concepts to Programmable Matter

Bacterial Nanocellulose-Based Electrochemical Biosensors: An Overview and Producing Graphene on the Spot

Emanuel Carrilho[1,2]

[1]Instituto Nacional de Ciência Tecnologia de Bioanalítica, [2]Instituto de Química de SãoCarlos
(*Departamento de Química e Física Molecular*)

e-mail: emanuel@iqsc.usp.br

Bacterial nanocellulose (BNC) has gained a promising role as an alternative to anti-fouling surfaces. BNC may form part of a support for immobilizing specific materials to widen its applicability as a biosensing device. The possibilities of modification methods and ***in situ***and ***ex situ***functionalization enable new BNC properties. With the new insights into nanoscale studies, we expect that many biosensors currently based on plastic, glass, or paper platforms will rely on renewable platforms, especially BNC ones. Recently, paper has become a simple and inexpensive platform for electrochemical detection creating a new generation of electrochemical paper-based analytical devices (ePAD), however. deposition of electrodes over paper can be difficult, but graphene production on site is simple if combining the production process with a CO_2laser scribing. This process results in a graphene porous material with a large specific surface area.

Design of catalyst modified electrode using organic-inorganic hybrid metal hydroxide salt monolayer nanoparticles

Naoki Tarutani[1], Sota Kimura[1], Shohei Futatsugi[1], Kiyofumi Katagiri[1], Kei Inumaru[1]

[1]Hiroshima University

e-mail: n-tarutani@hiroshima-u.ac.jp

Transition metal-based layered hydroxides are known as potential candidate catalysts for efficient oxygen evolution reaction. Since the finding about excellent electrochemical catalytic performance of exfoliated hydroxide nanosheets, many studies focus on the synthesis and catalytic use of hydroxide nanosheets/nanoparticles. In general, surface modifiers are necessary to synthe hydroxide nanosheets/nanoparticles to prevent aggregation and agglomeration. Surface modifiers will affect the electrochemical performance of hydroxides because electrochemical catalytic reaction will occur at the surface of the materials. However, there are scarce report. Here, we focus on the design of electrocatalyst modified electrode and effect of surface modifiers on the electrocatalytic performance of metal hydroxide nanosheets/nanoparticles.

Metal hydroxide nanosheets/nanoparticles were prepared based on our previous report.[1] Ethanolic solutions dissolving metal chloride and carboxylic acids were used as starting precursors. Addition of propylene oxide triggered pH increase and nucleation and crystal growth of metal hydroxide salt nanoparticles. Nanocolloids were collected after evaporation of residual propylene oxide. The Au electrode modified with self-assembled monolayer was dipped in nanocolloids to immobilize nanoparticles through interaction of organic groups. Electrocatalytic property of metal hydroxide salt monolayer nanoparticle was successfully measured and found to improve after electrochemical redox cycle. Compared with common metal hydroxide nanosheets, our metal hydroxide salt monolayer nanoparticles showed > 1000 times higher weight normalized catalytic performance. In addition, mesoporous Au electrode could be employed only for monolayer nanoparticles case, which enabled enhanced areal catalytic activity owing to the high specific surface area derived from mesoporous structure.

e-mail: luisa.decola@unimi.it

Advancements in the use of nanoparticles for biomedical applications have clearly shown their potential for the preparation of improved imaging and drug-delivery systems. However, only a few successfully translate into clinical practice, because the nanoparticle are uptaken by macrophages. We have recently reported disulfide-bridged organosilica nanoparticles with cage-like morphology, and assessed in detail their bioaccumulation in vivo. [1] The fate of intravenously injected 20 nm nanocages was investigated in both healthy and tumor bearing mice. Interestingly, the nanoparticles exclusively co-localize with hepatic sinusoidal endothelial cells, while avoiding Kupffer-cell uptake in both physiological and pathological condition. Such findings have been used to study the therapeutic effect of such nanocarriers for fighting cancer and in particular malignant pleural mesotelioma. We have stabilized, transported and intracellular released a platinumIV prodrug using the breakable nanocarrier. Its reduction, and therefore activation as anticancer drug, is promoted by the presence of glutathione in neoplastic cells that also causes the destruction of the carrier. In vivo data showed an interesting 50% reduction of tumor growth was observed when mice were treated with the PtIV, entrapped in the nanocages, at an equivalent dose of platinum complex. [2]In addition they are able to stabilize out of equilibrium species and transport them inside cells were they can be released and evolve towards the equilibrium state. [3] Both materials can be covered with a lipidic layer to improve the hemocompatibility and improve cell uptake rendering the nanomaterials biomimetic.

We wish to thank the European Union’s Horizon 2020 research and innovation programme under grant agreement No 964386 (FET Open Mimic-Key project).

e-mail: FSIGOLI@UNICAMP.BR

The engineering of hierarchically core@multishell nanoparticles containing heterogeneous crystalline phases in different layers constitutes an important strategy for obtaining luminescent probes. The possibility of obtaining an opto-magnetic core@multishell nanoparticle capable of emitting from VIS to NIR by upconversion, dowconversion and downshifting processes is highly desirable, especially when its optical responses are dependent on temperature or magnetic field variations. Our research group has great knowledge on synthesizing hierarchically structured NaREF4 core@multishell nanoparticles of heterogeneous crystalline phases, cubic or hexagonal, applied to magnetic or photophysical properties, respectively. The crystalline and compositional hierarchies are satisfactorily obtained and confirmed by DRX, EDS mapping and HAADAF images, allowing the optimization of optical or magnetic properties in different nanoparticle regions. Optically active shells emit in the VIS or NIR regions after excitation at 980, 808, and 1550 nm, covering different biological windows. The nanoparticle emissions are affected by temperature, where ErIII upcoversion, for example, may be taken as a temperature probe in a temperature range of 77 K to 427 K. Dowshifting emission in the NIR region covers higher temperatures ranging from 427 to 633K. The core@multishell nanoparticle can also have its luminescence modulated by the application of an external magnetic field that at low temperature improves the emission intensities and promotes the unfolding of Zeeman''s doublets of the Kramer ErIII ion. We also probed upconversion as a function of time and power of Surface Acoustic Wave (SAW), especially for high power regimes and low temperatures, the optical response indicates a considerable local temperature increase. Therefore, the magneto-optical properties of nanoparticles reveal their versatile nature and applicability as magnetic field or temperature luminescent probes.

Molecular-Electronic Switches that Mimic Synapses

Christian A. Nijhuis[1]

[1]University of Twente / Universiteit Twente (*Molecular Materials*)

e-mail: c.a.nijhuis@utwente.nl

Department of Molecules and Materials, MESA+ Institute for Nanotechnology, Molecules Center and Center for Brain-Inspired Nano Systems (BRAINS), Faculty of Science and Technology, University of Twente, P.O. Box 217, 7500 AE Enschede, The Netherlands.
C.A.Nijhuis@utwente.nl

Molecular electronic devices are highly complementary to traditional electronic devices and may lead, in principle, to novel functionalities that are very complicated to realize otherwise[1,2]. I will discuss our recent efforts to develop multi-functional molecular devices[3,4,5]. We developed a new type of an electrically driven molecular switch that can toggle between two different functionalities, that of a diode and memory.[5] This dual-functional switch resembles one diode-one resistor (1D-1R) resistive random access memory (RRAM) but defined within a single molecular layer greatly reducing the operatingvoltage (to just

Molecule/Framework orientation on inorganics for anisotropic electrical, optical and thermal properties

Kenji Okada[1]

[1]Osaka Metropolitan University

e-mail: k_okada@omu.ac.jp

Precise control of the material interface, i.e., lattice matching at the interface, is important for the fabrication of oriented thin films with sophisticated functionalities. In the field of inorganic materials, epitaxial growth by lattice matching at the interface has been deeply investigated and contributed to the development of semiconductor devices. We have been reporting unique organic-inorganic epitaxial interface on metal hydroxides, which affords orientation of organic molecules and the fabrication of oriented metal-organic framework (MOF) films[1-6]. Crystalline metal hydroxides have hydroxyl groups (M-OH units) regularly arranged on their surface of which alignment reflects their crystalline structure. The ordered array of hydroxyl groups defines the alignment of the organic molecules on the surface (organic-inorganic epitaxial interface), affording the fabrication of oriented MOF films [1]. Because the MOF micropores are aligned to the specific directions in the macroscopic scales in the oriented MOF films, thin films with anisotropic properties for advanced technologies including electronic, optical, and thermal devices can be achieved via a host-guest approach by an accommodation of functional guests (molecules, ions, or nano objects) into the pores. For example, oriented MOF films impregnated with fluorescent molecules exhibited polarization-dependent optical responses[3]. In this presentation, our resent progress on the fabrication and applications (unique optical, electrical, and thermal properties) of oriented MOF films will be reviewed.

Organic emitting compounds as smart molecular materials

Fabio Rizzo[1]

[1]University of Münster (*Center for Soft Nanoscience (SoN)*)

e-mail: fabio.rizzo@cnr.it

Light or electric pulses are commonly used as external stimuli in the field of smart materials to control the macroscopic behavior. At molecular level, the organization of molecules at the macro-scale as thin films or solids influences the color of the emitted light. Hence, a planned chemical design plays a pivotal role to tune the properties of the small compounds and then to the bulk. Among the chemical species, organic molecules offer a large palette of easily structural modifications due to their chemical versatility, which allows a fine tuning of their properties, thus of their applications. In particular, organic emitting compounds can be considered as smart molecular materials as effect of the changes on the photophysical and electrochemical properties upon specific interactions with other species or with themself. In this contributions, examples of molecular systems exhibiting modifications on their emission upon specific interactions, such as host-guest interaction,[1] aggregation-induced emission[2] and self-assembled monolayer[3] will be presented.

Organic-inorganic composites and aerogels

Sidney José Lima Ribeiro[1] [1]Universidade

Estadual Paulista / Instituto de Química

e-mail: sidney.jl.ribeiro@unesp.br

Bacterial cellulose (BC) is a biocompatible and nontoxic biopolymer that has been successfully used as a sustainable substrate for flexible organic light emitting diodes (OLEDs). Adding recycled polystyrene to transparent BC membranes new conformable OLEDs substrates are fabricated. Polystyrene found in expanded foam package waste isdissolved in d-limonene (a green solvent extracted from orange peels), sprayed on BC membranes and tested as substrates for OLEDs [1].

In another application the polystyrene/d-limonene solution was used to well disperse upconversion nanoparticles. The new ink was used in order to fabricate new QR-codes displayig the optical properties of the nanoparticles. Temperature sensing was demonstrated. [2]

Finally, we will show new aerogels organic-inorganic hybrids membranes composed of cellulose and MoS2. These membranes show promising behavior for application in in-flow water purification, representing a significant advancement in the use of selfsupported aerogel membranes for photocatalytic applications in liquid media [3]

Photoresponsive soft materials made by molecular self-assembly

Bart Jan Ravoo[1]

[1]University of Münster (*Center for Soft Nanoscience*)

e-mail: b.j.ravoo@uni-muenster.de

Self-assembly is emerging as a superior method to prepare responsive and adaptive nanomaterials. The structure and function of these materials is entirely determined by the dynamic and weak interactions of the constituent molecular "building blocks" of the material. Since the inherent interactions are weak, these versatile materials readily respond to even small changes and stimuli in their environment. Moreover, these materials are biomimetic and can contain large amounts of water, so that applications in biomedical technology are foreseen.

This lecture will highlight our recent work on self-assembled supramolecular nanomaterials that respond to light. In all these nanomaterials, molecular photoswitches are key components. The improved molecular design of photoswitches enables the bottom-up self-assembly of tailor-made functional materials and interfaces. Amongst others, light responsive hydrogels, foams, monolayers, adhesives and solids will be discussed.

Plasmonic hierarchical superstructures as highly efficient SERS substrates for applications in health and environment

Margarita Sánchez-Domínguez[1], M. Edith Navarro Segura[1], Ruben Darío Rivera Rangel[1], Alexandra Cárdenas del Toro[1], Edwin Adao Hernández Angulo[1], Jaime Alvarez Quintana[1], Juan Manuel Ceballos Guzmán[1], Ana María Arizmendi Morquecho[1]

[1]CENTRO DE INVESTIGACION EN MATERIALES AVANZADOS S. C. (*SUBSEDE MONTERREY*)

e-mail: margarita.sanchez@cimav.edu.mx

Currently there is a high demand for ultrasensitive sensors for both health and environmental applications, and both areas are closely related. The detection of contaminants in food, water, and in general in the environment is essential since many of these are usually harmful to health. On the other hand, the detection of cancer biomarkersin early stages of the disease is essential to have greater chances of success in its eradication. In recent years, plasmonic hierarchical superstructures have played an important role in the development of new sensors with high detection capacity. These materials can be used as SERS substrates, which base their detection principle on surface enhanced Raman scattering. In this talk, several strategies for the synthesis of plasmonic nano and superstructures will be presented, as well as the evaluation of their performance as SERS substrates for the sensing of model molecules, contaminants, drugs and cancer cell lines. Several synthesis strategies were used: chemical synthesis, electrodeposition, electrophoresis and galvanic replacement. Various nano and superstructures such as nanostars, nanoparticle-decorated nanodendrites, nanostructured hollow polyhedrons, among others, based on Au, Ag, Cu and their combinations, were synthesized. Some of the pollutants and biomolecules detected were: model molecules (rhodamine 6G, 4-aminothiophenol, crystal violet), emerging pollutants such as bisphenol A and triclosan, antibiotics such as tetracycline and vancomycin, and opioid analgesics such as tramadol. In addition, through adequate functionalization, it was possible to specifically sense a prostate cancer cell line (LNCaP). The results obtained show us the high potential of hierarchical plasmonic nano and superstructures for the development of ultrasensitive SERS substrates.

Simulation and Theoretical Studies on Nonequilibrium Processes of Soft Matter Near Interfaces

Qiyun Tang[1]

[1]Southeast University China (*School of Physics*)

e-mail: qtang@seu.edu.cn

In this talk, I would briefly summarize our main findings on the simulation and theoretical studies of nonequilibrium processsces of soft matter near distinct interfaces in the past 10 years. We focus on the physical aging of ultrathin polymer films at solid-vapor interfaces [1], the interfacial crystallization of polymers near solid-liquid-vapor interfaces [2], and the evaporation of binary solvents at liquid-vapor interfaces [3]. Given the computer simulations and dynamical mean-field theories, we provide physical explanations on some interesting phenomena, such as the slowing down of accelerated aging [1], the anomalous Ostwald ripening during the skin layer within the evaporative skin layer [2], and the evaporation-induced liquid expansion in binary solvents [3]. These findings might foster our fundamental understanding of the nonequilibrium processes of soft matter near interfaces and promote their practical applications.

e-mail: amontero_oleas@outlook.com

Protein transport in a nano-vehicle (NV) is envisaged for local treatments as the protein is protected from degradation during transport and once inside the target cell can be released by some external stimulus. Designing, modelling, and synthesizing complex nano-objects that integrate signals and functions is an open frontier and is a very active research topicwhere formidable advances have been made. However, the synthesis of these NVs still presents numerous challenges given the complexity of the system and the difficulty ofcontrolling the kinetic parameters.

Here we present the design and synthesis of mesoporous silica (MPS)-based NVs with a gold core (Au/mSiO2) that meet the basic requirements of adequate to pass through a cell wall, high loading capacity, stability during transport, and stimulus-triggered release of the protein at the target. In this presentation, we will focus on the synthesis pathways that provide reproducible and monodisperse Au/mSiO2 particles with pores suitable for trappinga protein by non-covalent interactions, diameter less than 100 nm, and thickness of the silica layer such that the protein can be released by plasmonic heating.

One-pot and seed-growth pathways were deeply investigated. Even one-pot is less time-consuming and scalable, Au/mSiO2 with better performance was obtained by seed-growth route in a biphasic medium. This synthesis provides particles with 100 nm diameter and pore distribution between 5 and 13 nm, determined by N2 adsorption, which remains unchanged up to 5 days in simulated biological media (PBS). These particles retain proteins (BSA, RFP) and enzymes (HRP) more efficiently than particles with 3 nm pores or non-porous particles, confirming that proteins lodge in the pores. In the case of enzymes, the activity is comparable to that of the enzyme in solution. These findings represent a promising stride towards the advancement of a NV for controlled delivery and release of enzymes into cells.

Designing Hybrid Functional Aerogels forEnvironmental Applications

e-mail: elias.p.ferreira@gmail.com

The world today confronts numerous environmental challenges that require the creation of functional materials with exceptional (photo)catalytic activity and superior adsorption capacity. Inorganic nanomaterials exhibit excellent performance in removing contaminants and adsorbing metals due to their unique electronic and surface properties. However, using nanomaterials in particulate form for water treatment applications is impractical, considering the related economic, energy, and operational difficulties associated with material recovery [1]. In this presentation, we will discuss our recent studies [2,3] exploring bacterial nanocellulose-based aerogels as a porous, mechanically-stable and flexible support for inorganic nanostructures in order to design hybrid aerogel membranes for in-flow photo-assisted water treatment. Combining sol-gel, hydrothermal and supercritical drying techniques, we achieved controlled deposition of mesoporous metal sulphide/oxide layers on bacterial cellulose (BC) nanofibrils, thus obtaining lightweight hybrid organic-inorganic aerogel membranes. The prepared hybrid aerogels were employed in a specifically designed membrane photoreactor for the photo-assisted removal of organic and inorganic contaminants, such as dyes and heavy metals. Correlation between synthesis, material characterization, structural, and photocatalytic properties has yielded significant insights into designing functional materials for in-flow photocatalytic water purification. The optimized hybrid aerogel membranes exhibit promising performance for application in in-flow photo-assisted water treatment, representing a significant advancement in the use of free-standing aerogel membranes for photocatalytic applications in liquid media.

Development of a thermoresponsive nanobiohybrid material to control enzymatic activity

Maíra Theisen[1], Heloise Ribeiro de Barros[1], Leandro Piovan[1], Izabel Cristina Riegel-Vidotti[1]

[1]Universidade Federal do Paraná (*Química*)

e-mail: theisen.maira@gmail.com

Smart materials are mainly responsive materials that have one or more properties that can be controlled by external stimuli. They became a key research topic because of their versatility to be applicable in many areas, such as controlled release, and sensors. In numerous studies, these materials can be combined with other materials or molecules, forming hybrid materials or composites aiming to create or improve some properties [1]. For this work, the thermoresponsive polymer poly(N-isopropylacrylamide) (PNIPAm) was combined with gold nanoparticles (AuNP) previously functionalized with the Candida antarctica (CALB) enzyme. The aim is to show that PNIPAm can be used to modulate the enzymatic reaction by variation of temperature. Even following different synthesis protocols, in which the addition of the enzyme occurred in different steps [2], the structures formed were stable and presented similar characteristics. Transmission electron microscopy (TEM) images indicated that the hybrid material has been obtained. The enzymatic activity showed that the immobilization of CALB still maintains good activity, while the reaction with AuNPs alone behaved similarly to autohydrolysis. The ability to control enzymatic reactions by temperature has significant applications in various areas, such as biocatalysis, and drug delivery systems.

e-mail: marius.kirsch@tu-darmstadt.de

Their aptitude for transport modulation of ionic species renders mesoporous ceramic polymer hybrid materials integral components of novel energy management, sensing, and molecular sieving strategies. Nature's unrivaled precision in ion transport evolves from pore architectures refined to the nanoscale and structurally adapted to the demands of the traversing ions. In search for a concept, transferring the structuring precision to artificial mesopores, the plasmonic field of Au nanoparticles, entrapped in mesoporous silica double layers at a defined z position, was employed as directing unit for nanolocal placement of pH responsive polymers. Following a visible light-induced, oxygen-tolerant (PET)-RAFT protocol, the localized surface plasmon-induced polymerization was identified in IR, TGA, and TEM.[1] With laser-driven polymer writing we present an additional robust tool for locally precise implementation of polymer functionalities into mesopores.[2] We further work on gaining deepened understanding of how fine-tuning of reaction parameters and selection of polymerization reaction affords local control over polymer placement. The technique is shown to be a gateway to polymer barriers, i.e., linear arrays of polymer spots down to 7 μm in diameter, in x/y direction,[2] thus paving the way toward control over ionic motion in 3D.

Naphthalenediimides(bis)urea supramolecular synthons to build up molecular (1D)-fibers

Eduardo Rezende Triboni[1]

[1]Escola de Engenharia de Lorena - USP (*Química*)

e-mail: tribonier@usp.br

Naphthalene diimides (NDIs) are excellent compounds to form supramolecular systems properly due their planar structure, p-acidity, well-defined photophysics, and relatively easy synthesis [1]. In the present study, NDIs-(bis)ureas were prepared with donor and acceptor groups in order to investigate aggregation in solution and figure out how these groups may interfere with the molecular packing, forming either segregated solids or blended ones. UV-vis and fluorescence measures pointed to electron donor/acceptor driven-interaction of the NDI-(bis)ureas, and FT-IR, NMR, PXRD and SEM analysis indicated the formation of blended fibers. Therefore, such outcomes emphasise the importance of the stereoelectronic groups for building molecular blends and trigger intermolecular interaction. Moreover, an overview of the concepts and perspectives of this fascinating area belonging to crystal engineering, in which this study is embedded, will be highlighted.

TPDH Nanotube: structural, mechanical and electronic properties.

Juan Rafael Gomez Quispe[1], Pedro Alves da Silva Autreto[1]

[1]Universidade Federal do ABC (*CCNH*)

e-mail: juan.gomez@ufabc.edu.br

Carbon nanotubes (CNTs) are highly sought after due to their unique mechanical, optical and electronic properties. They can be visualized as cylindrical tubes formed by rolling two-dimensional sheets of graphene, where the electronic properties of the tubes are dependent on their chirality and diameter. Although graphene is the most used structural base, it is theoretically possible to create NTs using other 2D carbon allotropes [1]. Some of the most widely studied allotropes are Graphenylene, Penta-graphene, HOP-graphene, TPDH-graphene, and others, which consist of networks of linear chain polygons ranging from tetragons to dodecagons [1]. TPDH-graphene, one of the last carbon allotrope, is composed of sp2 carbon rings with 4, 5, 12, and 6 atoms. It exhibits both thermal and dynamic stability, anisotropic elastic properties, and metallic behavior that can be altered by hydrogenation of the tetragonal rings [2,3]. In this work, we explore the structure, mechanical, and electronic properties of TPDH-NTs with chirality (n,0),(n,1), (n,n) for n 4, using density functional theory (DFT) and molecular dynamics (MD) calculations. Our preliminare results indicate that TPDH-NT (2,1) exhibits semiconductor behavior with a small indirect band gap, while other TPDH-NTs show metallic behavior. We observe the structural stability of TPDH-NT via MD at (T=300K), and the stress-strain profiles calculated by DFT and MD show a good correlation, coinciding at the fracture limit of the TPDH-NTs. These preliminary results suggest that TPDH-NTs possess distinct mechanical and electronic properties compared to TPDH-2D, especially TPDH-NT with chirality (2,1), which exhibits semiconductor behavior.

Characterization of the Thermodynamic and Kinetic Properties of Thermosensitive Composites for Controlled Drug Release

Arthur Martins Gabriel[1], Maria Luiza Lopes Sierra e Silva[2,1], Elaine Cristina Paris[2], Cauê Ribeiro de Oliveira[2], Emerson Rodrigues de Camargo[1]

[1]Universidade Federal de São Carlos (*Departamento de Química*) , [2]EMBRAPA Instrumentação

e-mail: arthurgabriel98@gmail.com

Smart polymers, known as stimuli-responsive polymers, are a class of materials that exhibit dynamic and reversible changes in their properties in response to external stimuli. Among them, the thermosensitive ones stand out for their ability to phase transition in response to temperature changes, which can result in changes in solubility, swelling and other physical properties and can be used in drug delivery, sensors and tissue engineering as this change occurs in a controlled and predictable way. However, the narrow transition temperature range of some materials is a challenge that implies modifying this phenomenon. The modification of this transition, and consequently of the properties of the composites, is done by adding nanoparticles to the polymeric matrix in order to change the temperature, width, and hysteresis of the polymer, providing a tunable and controllable phase transition behavior. The objective of this work was to study the influence of the addition of SiO_2 nanoparticles to the poly(N-vinylcaprolactam) matrix on its thermodynamic and kinetic properties, aiming at optimizing the transition profile for using the material in controlled drug delivery system. An in situ, polymerization of PNVCL was carried out in the presence of 20nm SiO_2 nanoparticles and the composites were subjected to optical, spectroscopic and physicochemical characterizations. The results showed a strong influence of the nanomaterial on the molecular mass and transition temperature of the PNVCL chains. It was observed that increasing NPs loading increased Mw, decreased LCST, and favored smoother transitions. Also, NPs increased initial polymerization speed but decreased conversion rates. Thus, this change in temperature and transition width allows the material to be used as a drug release vehicle in a satisfactory manner.

Graphene oxide-cobalt ferrite (GO-CoFeO4) nanocomposites have been recently explored as a promising sensors for the detection of breath biomarkers. The GO-CoFeO4 possess high sensitivity and selectivity towards various volatile organic compounds (VOCs) that are present in exhaled breath, which can be indicative of specific diseases or metabolic disorders. The cobalt ferrite nanoparticles improve the electrical properties of GO leading toa change in electrical conductivity of the nanocomposite thick films and better sensivity. A serie of nanocomposite were rationally sythesized leading to successfully detection of several breath biomarkers, including acetone, ammonia, formadehyde and alcohol. The PCA analysis showed specifics regions for each biomarker. The fabrication of GO-CoFeO4 nanocomposites is simple and cost-effective, making them a promising candidate for the development of low-cost and portable breath biomarker sensors for early disease diagnosi

Development of Hybrid Siloxane-Polyether Nanocomposites containing Superparamagnetic Nanoparticles for Future Applications in Drug Releaseby Magnetic Hyperthermia

Agnes Candido Teixeira[1], Natasha Midori Suguihiro[1], Benjamin Rache Salles[2], Wallace de Castro Nunes[3], Karim Dahmouche[1]

[1]Universidade Federal do Rio de Janeiro (*Campus UFRJ - Duque de Caxias*) , [2]Universidade Federal do Rio de Janeiro (*Instituto de Fisica*) , [3]Universidade Federal Fluminense (*Instituto de Física*)

e-mail: agnescteixeira@gmail.com

In this work siloxane-polyether (PEO or PPO) hybrid nanocomposites containing □-Fe_2O_3 nanoparticles functionalized with Triethyleneglycol (TEG) have been prepared by Sol-Gel process, aiming future applications of controlled drug-delivery by magnetic hyperthermia. The magnetic particles were prepared by solvothermal method in a microwave reactor, and dispersed in the hybrid sol during the hybrids synthesis. X-ray Diffraction measurements (XRD) showed the characteristic crystalline phases expected for □-Fe_2O_3 superparamagnetic nanoparticles, whereas Dynamic Light Scattering (DLS) and Transmission Electron Microscopy (TEM) revealed that particles are monodispersed, with ranging from 5 to 15 nm, depending on synthesis condition. Magnetic analyses showed that, at room temperature, the particles exhibit a superparamagnetic behavior and that the dipolar interaction between the nanoparticles is weak. Magnetic hyperthermia measurements have been carried out with the synthed particles, to determine the optimal conditions (amplitude and frequency of the magnetic field) that lead to the optimum heat generation. The first synthesis of the hybrid nanocomposites evidenced the possibility to incorporate significant amounts of magnetic particles in Siloxane-PEO hybrid matrix, due to the hydrophilic nature of TEG and PEO, while dispersion of the particles in the more hydrophobic Siloxane-PPO matrix is inhibited. These preliminary results are promising for the future development of biocompatible, transparent and flexible hybrid films presenting high stability in biological media, which may be employed for drug release in human skin by magnetic hyperthermia.

Dip Pen Nanolithography of Gold and Magnetite Nanoparticles

Lisa Schlichter[1,2], Florian Bosse[1,2], Bonnie, J. Tyler[1,3], Heinrich F. Arlinghaus[1,3], Bart Jan Ravoo[1,2]

[1]Universität Münster (*Center for Soft Nanoscience*) , [2]Universität Münster (*Organic Chemistry Institute*) , [3]Universität Münster (*Physics Institute*)

e-mail: l.schlichter@uni-muenster.de

Nanoparticles offer unique physical and chemical properties. Dip pen nanolithography of nanoparticles enables versatile patterning and nanofabrication with potential application in electronics and sensing, but is not well studied yet. Herein, the patterned deposition of various nanoparticles onto unmodified silicon substrates is presented.[1] It is shown that aqueous solutions of hydrophilic citrate and cyclodextrin functionalized gold nanoparticles as well as poly(acrylic) acid decorated magnetite nanoparticles are feasible for writing nanostructures. Both smaller and larger nanoparticles can be patterned. Hydrophobic oleylamine or n-dodecylamine capped gold nanoparticles and oleic acid decorated magnetite nanoparticles are deposited from toluene. Tip loading is carried out by dip-coating, and writing succeeds fast within 0.1 s. Also, coating with longer tip dwell times, at different relative humidity and varying frequency are studied for deposition of nanoparticle clusters. The resulting feature is between 300 and 1780 nm as determined by scanning electron microscopy. Atomic force microscopy confirms that the heights of the deposited structures correspond to a single or double layer of nanoparticles. Higher writing speeds lead to smaller line thicknesses, offering possibilities to more complex structures. Dip pen nanolithography can hence be used to pattern nanoparticles on silicon substrates independent of the surface chemistry.

e-mail: joao.antonio@unesp.br

Metal-Enhanced Luminescence (MEL) is an effect explored to enhance the emission intensity and maximize other photophysical parameters of lanthanide ions (Ln3+) that are nearby plasmonic nanostructures such as metallic gold or silver nanoparticles [1]. Here, the objective was to evaluate the luminescent and biological properties of plasmonic nanostructures (Ag@SiO2) functionalized with luminescent europium complexes (Eu3+-complex). The development of such structures was performed in several reaction steps. First, citrate-stabilized 30 nm-AgNP were covered with silica thickness of 37 or 53 nm, resulting in the Ag@SiO2 structures, which were later functionalized with APTES (3-aminopropyltriethoxysilane) and, finally, had their amino groups reacted with the epoxide group present in the previously synthed complex [Eu(TTA)3ephen], TTA = 2-thenoyltrifluoroacetone, and ephen = 5,6-Epoxy-5,6-dihydro-[1,10] phenanthroline. Photoluminescence analysis showed that the presence of AgNP enhanced the emission of the anchored complexes by a factor of 17 times when compared to the emission of the materials used as blank (50 and 170 nm silver-free silica nanoparticles functionalized with the same Eu-complexes). Cytotoxicity assays on liver cancer cells, Huh 7.5, and confocal microscopy measurements showed that the plasmonic structures were non-toxic at 25 mg/mL and were internalized by cells, preserving the Eu3+ red-emission and the cell structure.

Epoxy-silica anticorrosive coatings modified with Ce (III) and Ce (IV) ions with self-healing properties

Adriana Araújo Almeida[1], Mayara Carla Uvida[1], Peter Hammer[1], Celso Valentim Santilli[1]

[1]Universidade Estadual Paulista / Instituto de Química

e-mail: adriana.a.almeida@unesp.br

Coatings with an efficient anticorrosive barrier are essential for the protection of metal surfaces, however over time the coated substrate becomes susceptible to localized corrosive action and physical damage, such as cracks and scratches, reducing its protection efficiency. To ensure long-term protection against corrosion, coating systems must combinea dense and effective passive barrier against the permeation of oxidizing species and active protection of surfaces through a self-healing capacity after failures. The self-healing property can be achieved with the addition of self-healing agents, such as Ce(IV) and Ce(III) ions. In this context, hybrid epoxy-silica coatings were modified with the incorporation of cerium salts (Ce(NO3)3.6H2O), (NH4)2Ce(NO3)6) varying the molar concentration between 0.5 and 5.0 % of Ce(III) and Ce(IV), in relation to the total silica present in the hybrid. The epoxy-silica hybrids were prepared from the curing of poly(bisphenol-A-co-epichlorohydrin) (DGBEA), (3-glycidoxypropyl)trimethoxysilane (GPTMS) and diethyltriamine (DETA), combined with hydrolysis and condensation reactions of tetraethoxysilane (TEOS) in aqueous acidified ethanol. Films with a thickness of about 15 μm were deposited by the dip-coating method on aluminum alloy yielding and adhesion strength of 20 MPa. To evaluate the effect of the addition of Ce(III) and Ce (IV) ions on the nanostructure formation, SAXS, FTIR, TG and contact angle measurements were used. The results obtained by electrochemical impedance spectroscopy in NaCl solution showed a high corrosion resistance of the coatings with low-frequency impedance (4 mHz) of about 100MΩcm2, that is, 5 orders of magnitude higher than the bare substrate. The self-healing effect was evaluated for scratched coatings after immersion in saline solution. After 10 days it was possible to observe a recovery of the impedance modulus, evidencing the self-healing ability of the coatings.

Hybrid urethane films based on PDMS and OGPOSS: Synthesis via CO2 fixation and evaluation of its antimicrobial activity.

In this study, we have developed potential antimicrobial polymeric films for possible applications as antimicrobial metal coatings. The precursors were prepared by the reaction between carbon dioxide and polyepoxides, in order to obtain cyclic bis- and octa-carbonate (CC''s). Thus, these CC''s were reacted by aminolysis with isophorenediamine and an aminopropytriethoxysilane, leading to the formation of non-isocyanate (poly)urethanes (NIPU''s) derived from poly(dimethylsiloxane) (PDMS) and octaglycidyldimethylsilyl polyhedral oligomeric silsesquioxane (OGPOSS). Finally, self-supported hybrid films of these NIPU''s were obtained through the sol-gel process, catalyzed by phosphotungstic (PWA) or phosphoric (H3PO4) acid. The precursor CC' s and the hybrid films were characterized by the techniques of Energy Dispersive X-ray Fluorescence Spectroscopy (EDXRF), Fourier Transform Mid-Infrared Absorption Spectroscopy (FTIR), Raman Spectroscopy and Nuclear Magnetic Resonance (NMR). In addition, the films were preliminarily tested for bactericidal activity for Staphyloccocus aureus. The acid incorporation into the urethanes improved the antimicrobial activity from bacteriostatic to bactericidal. Higher concentrations of CCOGPOSS also implied an improvement in antimicrobial activity.

In-situ polystyrene/BaSO4 nanocomposites via multiple sequencial microemulsions using phase inversion temperature (PIT) as emulsification low-energy technique

Rafael Caetano Jardim Pinto da Silva Salvato[1], Amilton Martins dos Santos[1] [1]Escola de Engenharia de Lorena da Univerdade de São Paulo (*Engenharia Química (LOQ)*)

e-mail: rafaelcaetano@usp.br

Polymer/inorganic nanocomposites have received considerable attention of academic and industrial research as the incorporation of nanofillers within a polymer matrix often leads to materials with enhanced mechanical, thermal, or barrier properties, even at low inorganic contents [1]. However, obtaining these nanoparticles as well as stabilizing them proves to be a particularly challenging task, mainly via heterophase polymerization in aqueous media. Several works in the literature have been reported for miniemulsion polymerization as an alternative to overcome these drawbacks, however with the help of poorly available and expensive reagents, or even using specific equipment with clear limitations of scale-up to industrial end-use, what severely limited their adoption by the main targeted end-applications [2]. In this context, the sequential processing of multiple reactions in mini emulsion, using conventional reactors, presents itself as an interesting alternative to achieve the objectives, both for the generation of inorganic nanoparticles and the respective hybrid latexes. This work aims to carry out a model study to enable both guided and in-situ synthesis of inorganic nanoparticles of BaSO4 to act as pigments, as well as that of hybrid latices of polystyrene/BaSO4 as seed for acrylic film-forming agents, base materials for water-based decorative paint formulations, obtained through the sequential processing of multiple (mini)emulsions using a combination of low-energy technique with temperature induced emulsification (PIT) and catastrophic phase inversions, using technical grade nonionics and anionic as surfactants in this two-step radical polymerization approach.

Upconversion nanoparticles (UCNPs) have high versatility of application and are capable of emitting light with a wavelength shorter than the excitation, converting low-energy light into high-energy light. UCNPs have been used in various applications, but it is probably in the field of detection that they best demonstrate their potential. Thanks to the possibility of controlling cytotoxicity, high photo-stability, large anti-Stokes shifts, long lifetimes, and reduced background noise, which significantly increases the limit of detection (LOD), the emerging field of UCNP-based sensors is rapidly evolving through various approaches. We designed matrices of NaYF4 and NaGdF4 varying the pairs of doping ions Yb3+/Er3+ and Yb3+/Tm3+. With excitation at 980 nm, Er3+ presents emission peaks around 520, 540 and 650 nm and Tm3+ around 350, 450, 480 and 650 nm. Since UCNPs allow the use of low-energy excitation wavelengths, it is possible to achieve ideal energy excitation windows in the biological sensors, gaining particular prominence in this field. Also, within the scope of sensors and lanthanide-doped nanomaterials, we studied Nd3+-doped nanoparticles (Nd-NPs). Exciting these nanoparticles at 808 nm, emission peaks arround 880 and 1060 nm were analized to be used as parameters for temperature sensors in nanothermometry. Thus, in this work we optimized the synthesis by high temperature coprecipitation and characterize NPs consisting of different matrices and doping ions. For the UCNPs, the exchange of Y3+ for Gd3+, with both doping ions, showed a noticeable diameter reduction of approximately 3,5 - 4,6x with maintenance of luminescent properties and crystalline phase. On the other hand, the thermometric characterization of Nd-NPs are still in progress but already shows promising luminescent results. In this way, the poduced materials present potencial to be used in different multifunctional platforms in order to achieve the desired applications.

Nanostructured coatings based on copper/functionalized carbon nanotubes doped withiodine (Cu/NTC-f-i)

New nanostructured conductors developed from the coating of aluminum wires Al 1350 by copper/carbon nanotubes functionalized and doped by iodine (Cu/NTC-f.i), using the process of electrophoretic deposition in copper sulfate solution, under electric currents of 1.2 to 1.8 A, have been investigated for their electrical properties. The Al@Cu/NTC-f.i conductors were characterized by scanning electron microscopy; X-ray diffractio Raman spectroscopy, in addition to electrical measurements, at room temperature and under heating, via a Kelvin bridge. The results show an increase of approximately 18% of the IACS with good stability under heating compared to the commercial aluminum conductor Al 1350, due to the intrinsic properties of the functionalized CNTs and the doping effect of the iodine, confirmed by Raman spectroscopy with redshifts effects in the sub- G-band bands, in addition to ACD calculation and FWHM data. The characteristic morphology of the Cu/CNT-f thin films showed pyramidal structures, agglomerates, copper structures involving the CNTs, as well as CNTs homogeneously electrodeposited on the aluminum substrate withgood crystallinity, cultivated mainly in the directions (311) and (111). This Cu/NTC-f.i electrodeposition method on the surface of metallic wires shows promise for the productionof nanostructured metallic conductors with high ampacity, thermal stability, low density andhigh performance, applied in electric energy transmission lines. for application in power transmission lines.

SiO2/graphene oxide nanocomposite obtained from rice husk pyrolysis

Douglas de Souza Rocha[1,2], Jéssica Menezes de Mélo Luzardo[3], Joyce Rodrigues Araujo[4]

[1]Universidade Federal do Rio de Janeiro, [2]Instituto Nacional de Metrologia, Qualidade e Tecnologia (*dimat*) , [3]Instituto Nacional de Metrologia, Qualidade e Tecnologia (*DIMAT*) , [4]Divisão de Metrologia de Materiais

e-mail: douglas.souzar@outlook.com

Rice husk contains cellulose, hemicellulose, some inorganic materials such as silica and a considerable percentage of lignin, the second most abundant natural polymer in nature [1]. Previous studies have shown that the crystallinity of carbon materials such as lignin can be improved by exposure to high temperatures, typically greater than 700°C, in an inert atmosphere [2,3]. In this work, the thermoconversion of rice husks was carried out to produce a SiO2/graphene oxide nanocomposite, where the lignin nanocarbon is a dispersed phase in a silica matrix. The silica is present in the basal plane of the rice husk, and after lignin thermoconversion, the produced nanocomposite was incorporated into cementitious pastes, providing improved resistance to compression. The chemical structure of the rice husk was modified by a controlled routine based on sequential irradiation with ultraviolet light, hydrothermal carbonization in an autoclave, vacuum degassing, pyrolysis and mechanical exfoliation. The SiO2-GO nanocomposite was characterized by X-ray diffraction, Fourier-transformed infrared and Raman spectroscopies and X-ray photoelectron spectroscopy. The thermal treatment performed was not sufficient to degrade the silica, allowing only the transformation of the lignin present in the rice husk in a nanoporous carbon structure composed of sp2 hybridized lignin structure with oxygenated functional groups attached to this structure. The Raman and infrared spectra revealed the presence of two phases in the structure, one related to the carbon crystallite grains and the other related to silicates, reinforcing the idea of a nanocomposite between the two phases.

Sound crystallization of anthranilic acid polymorphs

Yasmin Caroline da Silva Figueiredo[1], Eduardo Rezende Triboni[1]

[1]Universidade de São Paulo (*Chemical Engineering - EEL/USP*)

e-mail: figueiredoycs@usp.br

Anthranilic acid (AA) crystals are known in three polymorphic forms, form I (AMBAC007), form II (AMBAC005), and form III (AMBAC008). Phase I is triboluminescent, that is, ability to emit light when it is under pressure or sudden extension. Further, phase I has unit cells with polar space groups, while phases II and III are nonpolar [1]. We have developed a mechanical-acoustic system to crystallize separately AA polymorphs. The procedure consisted in preparing a supersaturated solution of AA (solute) in distilled H2O (solvent) in a recipient (Teflon or stainless steel), then, it was put on plate under sound waves with certain low frequency and intensity. Once crystals solidified out, they were filtered off and dried in an oven at 70°C for 24 hours. Solid phases were identified by PXRD and irradiation underUV light (l = 365 nm). Depending on the acoustic setup it was observed both concomitant polymorphs and pure (single phase) crystals. So far, it is the first description of crystallizing different AA solid forms from the same solvent. Moreover, such unprecedent mechanical-acoustic crystallization is rather promising for both supramolecular chemistry area and industrial crystallization operations.

Sounds waves for generating polymorphic crystals ofROY

Jonas Luis Massuchini de Carvalho[1], Eduardo Rezende Triboni[1]

[1]Escola de Engenharia de Lorena da Univerdade de São Paulo

e-mail: jooh1324@usp.br

The new mechanical acoustic method for generating polymorphic crystals is a revolutionary approach to crystallization. The process occurs out of equilibrium, using a supersaturated solution of 5-methyl-2-[(2-nitrophenyl)amino]-3-thienylacetonitrile, or ROY (Red, Orange and Yellow), a substance with approximately 12 different polymorphs cataloged [1] in distinct solvents such as isopropyl alcohol and ethanol. The solution is placed in a container (teflon or stainless steel) and subjected to low-frequency, low-intensity sound waves, causing vibration on a plate. By varying the frequency and intensity of the sound waves, different or concurrent polymorphs can be generated, with variations in their growth axes and consequently resulting in distinct colors. This method allows for the reproduction of polymorphs based on the specific variations of the frequency and intensity of the sound waves applied. Once crystals are formed, the solution is filtered and dried in a 70°C oven for24 hours. Solid phases are identified by PXRD. Therefore, the use of this mechanical- acoustic method can greatly innovate industrial and supramolecular crystallization.

Medical advances have improved the survival of cancer patients. Nevertheless, the lack of distinction between normal and tumor cells causes several side effects. Therefore, the scientific community has explored the development of pH-responsive polymeric systems, that can promote drug delivery to cancer cells. Furthermore, these polymers can be associated with materials such as mesoporous silica, hydroxyapatite, and rare earth elements, to obtain a multifunctional system that can act in therapy and diagnosis simultaneously, known as theranostic materials. Mesoporous silica has exciting properties as the high surface area and hydroxyapatite have been widely studied to aid bone regeneration. When associated with rare earth elements, such as europium, and gadolinium, these materials become the potential for imaging diagnosis. Therefore, the objective of the present work is to obtain a hybrid system responsive to pH based on silica and hydroxyapatite with photoluminescent and magnetic properties. The materials were characterized by FTIR, XRD, SEM, TGA, XPS, superficial analyses, photoluminescence, and zeta potential techniques. Incorporation and release studies of the antitumor drug doxorubicin were carried out to evaluate the potential use of these systems in the targeted delivery of drugs. The results evidenced the luminescent and magnetic properties of the materials and showed characteristics suitable for application in pH-sensitive drug delivery.

e-mail: bianca.mattos@usp.br

The field of photoactive device design has received significant attention in recent years due to its impact on technological advancements. One promising approach to enhance the performance of these systems is to prepare semiconductor oxide nanocomposites with metals or metal complexes. This can lead to improvements in (photo)catalytic activity, stability, solar energy conversion, and the addition of new properties. Core@shell nanocomposites are particularly interesting due to their ability to tune structural and electronic properties by modifying the composition and physicochemical properties of their core and shell components [1].

In this study, we explore the modification of titanium oxide-based photocatalysts with hexacyanometallate Ferric Ferrocyanide, also known as Prussian Blue (PB). Titania-silica aerogels decorated with PB (ae-SiO_2@TiO_2@PB) were synthed combining sol-gel and photodeposition methods techniques. We studied the photochromic properties of titania silica aerogel decorated with PB dispersed on thin films based on hydroxiurethane/polydimethylsiloxane (PDMS) urethanesil type hybrid [2]. Prepared hybrid films show reversible photochromic behavior based on photo-induced reduction of PB layer by anatase nanocrystals under UV-light. Our results suggest that semiconductor@PB core@shell nanocomposites have promising potential for the design of photoactive devices in a variety of applications, including photochromic thin films, solar cells, and photocatalytic surfaces.

Transmission of acoustic waves and logic operations onY-shaped nonlinearly coupled harmonic chains

Samila Ferraz da Silva Oliveira[1], Marcelo Leite Lyra[1]

[1]Universidade Federal de Alagoas (*Instituto de Física*)

e-mail: samila.oliveira@fis.ufal.br

We investigate the propagation of acoustic waves on Y-shaped coupled harmonic mass-spring chains and discuss the possible realization of logic functions. Non-linear contributions to the coupling among the three semi-infinite chains are considered. The stationary scattering theory is used to obtain exact expressions for the transmission spectrum on the output channel for the cases of incident waves coming from a single or both input channels. Special features related to the nonlinear character of the coupling are explored including bistable behavior and self-induced transparence. Considering an amplitude modulated protocol with a threshold transmission level, we explore the possible realization of logic functions. We determine the spectral regions for the realization of different logic operations as a function of the wavenumber of the incident normal modes and the relative phase difference between them.

C-Multifunctional Polymer Blends and Composites

On a layered composite coating with piezoresistivity and mechanoluminescence properties for wearable sensors

Marino Lavorgna[1], Jize Liu[2]

[1]National Research Council of Italy, Institute of Polymers, Composites and Biomaterials (*DSCTM-CNR*) , [2]State Key Laboratory of Polymer Materials Engineering, Polymer Research Institute, Sichuan University

e-mail: marino.lavorgna@cnr.it

The development and validation of a multifunctional composite material with visible sensing behavior remains still a challenge. However, graphene and its derivatives, represent a valid tool to design responsive materials, through a fine controlling of their spatial distribution and interfacial interactions with polymeric phases [1, 2]. Here we present a smart fabric with piezoresistivity and mechanoluminescence ability based on a layered structure made of graphene-modified conductive cotton fabric and $SrAl_2O_4:Eu^{2+}$, Dy^{3+}/polyurethane foamed coating. The presence of the layered structure endows the flexible composite fabric with a controllable positive/negative piezoresistivity (gauge factor from -2.5 to 17) and a bright mechanoluminescence ability that can be used in the darkness to detect specific deformations, without additional batteries. Three-dimensional chromaticity diagrams have also been developed as advanced tools to quantitatively assess the luminescence, whose lightness during the bending cycles is highly repeatable. The multifunctional layered composite coating provides multiple output signals which can be accurately recognized and assigned to independent triggering events, opening up to new opportunities in advanced wearable devices based on commercial fabrics [3].

Towards smart circular manufacturing strategies - a materials revalorization perspective

Lucas A. Hof[1]

[1]École de Technologie Superieure (*Mechanical Engineering*)

e-mail: lucas.hof@etsmtl.ca

Humanity faces dramatic challenges, as humanity is exhausting nature’s budget progressively each year. At the same time, waste is growing exponentially; consumption reduction, reusing and recycling are no longer options but vital for sustainable human activities on earth. The concept of a circular economy aims to address these issues by closing the material loop across the full supply chain. Yet, significant barriers prevent its full adoption. Major ones being lack of information on the product life cycles and shortage of advanced technologies for remanufacturing and novel reverse supply chain strategies for material revalorization. Research on taking advantage of smart technologies to unlock the full potential of circular manufacturing approaches is just starting.

Besides the discussion on intelligent CLSC approaches, ongoing research activities on sustainable material development and a framework for study on improving performance of circular manufacturing will be presented.

3D printing of electrically conductive polymernanocomposites for fuel cell applications

Luis Marcelo Garcia da Silva[1], Tamara Chalegre[1], Lucas Y. M. Rodrigues[1], Lívia P. Santos[1], Paulo H. R. Dantas[1], Thiago N. Viana[1], Suel Eric Vidotti[1], Anibal de Andrade Mendes Filho[2], Danilo Justino Carastan[3]

e-mail: luis.garcia@ufabc.edu.br

Extrinsic electrically conductive polymer nanocomposites can be produced by adding conductive nanoparticles to a polymer matrix. In particular, carbon-based nanomaterials, such as graphene, carbon nanotubes and carbon black, are effective to increase the electrical conductivity of polymers without changing the weight of the material significantly [1]. Fuel cells can take advantage of such materials, especially when related to automotive applications. Fuel cell parts such as bipolar plates can be made lighter than usual if produced from conductive polymer nanocomposites [2]. Additive manufacturing can also be an important ally in the production of such devices, as the design of the parts can be promptly adjusted and optimized in an iterative manner [3]. In this work, different types of thermoplastics were combined with carbon-based nanomaterials, to produce a series of electrically conductive nanocomposites. The samples were prepared by twin screw extrusion and solvent-assisted techniques, and their electrical, mechanical and rheological properties were characterized. 3D printing filaments were subsequently produced and used to print test samples and prototypes of bipolar plates for fuel cell applications. High electrical conductivity was reached by a series of samples, depending on their composition, type of conductive filler and processing technique used. The direction of 3D printing also affected the final conductivity and overall performance of the printed samples.

e-mail: dhonatacaldas@gmail.com

Due to the Industry 4.0, factories are increasingly dependent on the Internet and communication technologies, which guarantees unprecedented efficiency, but can also lead to vulnerabilities [1]. For this reason, cybersecurity is an increasingly relevant topic, with technologies such as physically unclonable functions (PUFs) and quantum cryptography being good alternatives in this area [2]. For this reason, this work presents the development of a nanocomposite of poly(acrylonitrile-butadiene-styrene) (ABS) and carbon nanotubes (CNTs) for the 3D printing of so-called NanoCodec, which present spectral signatures that can be used as PUFs in quantum cryptography. For this, ABS/CNTs nanocomposite filaments were produced, with 1 and 2 wt% of CNTs, for printing the NanoCodecs in quickresponse code (QRcode) and in circular/square stamps by fused deposition modeling (FDM). Raman spectroscopy was used to characterize the pure materials, both ABS and NTCs, andcompare them with the nanocomposites of ABS/NTCs. This showed an overlap of somebands associated with each material, particularly in the 1580-1620 cm-1 region, where vibrations of both CNTs and ABS carbon-carbon bonds are present, indicating the interaction between them and that the Raman spectrum is affected by the nanocomposite production process, so the random arrangement of CNTs in this material could be used as PUF quantum keys for encryption. Lastly, a mobile app was developed to read the QRcode, encrypt the Raman Spectra of the NanoCodecs, obtained from a Handheld Raman Spectrometer, on a 20-character alphanumeric key to validate the information on a server, which can be used to give trustworthiness on production chains of Industry 4.0.

Development of a Nanoimprinting Process for Antireflective Glass Surfaces

Douglas F Cole[1], Lucas A Hof[1], Ricardo J Zednik[1]

[1]École de Technologie Superieure (*Génie Mécanique*)

e-mail: douglas.cole.1@ens.etsmtl.ca

Antireflective (AR) surfaces are critical developments for electronic displays, solar panels, LED/OLED lighting, and lenses. Biomimetic moth-eye nanostructures offer significant reductions in glass reflection across the visible and near-IR spectrum and are self-cleaning due to their hydrophobic nature. However, current manufacturing methods for AR glass surfaces require clean-room environments and expensive machinery. In order to help the wide-scale adoption of AR glass for solar panels, it is important to further optimize the manufacturing process for these AR surfaces. Nanoimprint lithography (NIL) is a low-cost and high throughput patterning process which is well studied for low transition temperature polymers. Though promising for the large-scale production of AR patterns, high transition temperature glass NIL remains difficult due to the fragility of glass and the precise control required for the high processing temperatures and pressures. This research aims to develop an equipment and process for glass NIL. Ceramic micropatterned moulds were created by Laser-Induced Plasma-Assisted Ablation (LIPAA) and a high temperature testbench compatible with MTS compression machines was developed to replicate mould features. This study will provide finite element analysis (FEA) comparisons to the experimental results to optimize this novel process for high throughput glass imprinting.

Evaluation of physical-mechanical properties ofparticleboards bound with polyethylene terephthalate andcastor oil-based polyurethane resin

e-mail: rodrigoandrausbispo@gmail.com

Consumption of natural resources and waste generation has increased significantlyin recent decades. Polyethylene terephthalate - PET is a material widely used for variouspurposes such as in the packaging sector, however, the search for new methods to recycle thismaterial has been significant. Wood, on the other hand, is a natural resource used in theproduction of furniture and structural elements in civil construction, however, its processinggenerates a lot of waste, such as shavings that can serve as an alternative material inreplacement for the raw material for the production of particleboards. In this workparticleboards were produced with pine wood waste, PET particles and polyurethane adhesivederived from castor oil —PUR in the proportions of 50% PET, 50% pine and 10% PUR. Twogroups were studies changing the pressing temperature - 130ºC and 160ºC. Foreach group, 3panels measuring 35x35cm were produced, and their specimens tested for physical andmechanical properties. The results allowed verifying mechanical resistances much higher thanthose required by the Brazilian normative document.

In Brazil, the development of cities has led to the intensification of the exploitationof natural resources. Wood is an example of a versatile resource of great economicimportance to humanity, which is often exploited inconsequentially. An important aspect tobe considered in this study is the use of alternative materials aimed at their use in theproduction of particleboards, consequently, wood particleboards with the addition of sisalfiber were produced and evaluated. In this work, particles of wood from reforestation andsisal fiber were used with nominal density of 0.6 g/cm3, bonded with 10% castor oil-basedpolyurethane resin (PUR) and pressed at a temperature between 150 and 160 °C. Twomixtures were proposed and three panels were produced for each mixture, totaling six panels.For the first mixture, the fibers were distributed close to the surface of the panels and for thesecond, the fibers were distributed in four layers inside the panels. Based on the resultsobtained, it was verified that the addition of sisal fiber resulted in similar performance of thepanels in terms of their physical and mechanical properties and met the criteria proposed byNBR 14810-2/2018.

Polymeric membranes are applied for wastewater and unhealthy water filtration to contain the action of biological contaminants (bacteria and viruses), wastes from industrial, laboratory, pharmaceutical, and home activities, agriculture, and energy generation [1]. The filtration process can be classified by reverse osmosis, electrodialysis, nanofiltration, ultrafiltration, microfiltration, and distillation membranes [2]. The most common methods of manufacturing polymer matrix membranes are phase inversion, sintering, stretching, track-etching, and electrospinning. There is also the development of thin film nanocomposite membranes, which are developed by in situ interfacial polymerization, dip coating, layer-by-layer assembly, self-assembly, physical, and chemical deposition, chemical grafting, and corona plasma-assisted coating [3]. Nanocomposite materials are good for the reinforcement of polymer matrix membranes due to their high specific area and the fact that they can enhance their capacity to adsorb contaminants of the water, including chemical reagents, such as methylene blue and oxy-halogenates. Many researchers in the world are studying new materials to reach new economic, ecological, and technical advantages, especially nanomaterials. The aim of this study is to compare several processes of filtration, as well as identify and differentiate the application of each one. For this, results from literature were collected about the properties and characteristics of each filtration membrane.

Mechanical Properties of Mixed-Matrix MembranesUsing Coarse-Grained Simulations

Daniela Andrade Damasceno[1], Caetano Rodrigues Miranda[1], Erich A. Müller[2] [1]Instituto de Física/USP (*Departamento de Física dos Materiais e Mecânica*) , [2]Imperial College London (*Department of Chemical Engineering*)

e-mail: daniela.damasceno@usp.br

Mixed-matrix membranes (MMMs) are a promising technology to decrease CO_2 emissions by incorporating advanced fillers in their polymer matrices. Carbon nanotubes, for instance, may improve the selectivity/permeability trade-off in traditional polymeric membranes and enhance mechanical stability depending on their density and polymer affinity. Computational simulation modelling is a more efficient and cost-effective way to calculate these properties compared to experimental methods. This study established an effective simulation protocol using Coarse-Grained (CG) molecular simulation to study the mechanical behaviour of MMMs. The novelty of the approach is using the statistical associating fluid theory (SAFT-γ Mie) model to correlate experimental thermophysical properties of small molecules and produce reliable and versatile CG molecular parameters for large systems such as polymers [1]. These parameters can be directly used for Molecular Dynamics (MD) simulations. To parameterise the CG model of single-walled carbon nanotubes (SWCNTs), we used the Morse and Tersoff potentials. For the polyethylene, we used appropriate experimental data to obtain the intramolecular parameters and classical force fields for the intermolecular parameters through MD simulations. The results show that both CG models are suitable for reproducing the mechanical response of individual polymers and SWCNTs compared to the atomistic results. Additionally, the findings suggest that long SWCNTs may enhance the tensile strength of MMMs compared to a pure polymeric matrix. In contrast, short nanotubes have no significant effect on their mechanical response.

Nanocarbon obtained from lignin pyrolisis as a reinforcing agent in polyamide-6 nanocomposites

Sanair Massafra[1], Joyce Rodrigues Araujo[2]

[1]Instituto Nacional de Metrologia, Qualidade e Tecnologia (*Divisão metrologia de Materiais*) ,
[2]Divisão de Metrologia de Materiais

e-mail: smassafra-prometro@inmetro.gov.br

Nanocomposites based on polyamide-6 (PA-6) reinforced with graphene oxide (GO - Graphene Oxide) have been the subject of intense research due to their special characteristics, providing great industrial applicability in several areas, such as the civil construction industry, electronics and automotive sector. Studies focused on these nanocomposites are typically associated with the improvement of their mechanical properties (tensile strength and modulus of elasticity) and thermal properties. The aim of this work is to manufacture an alternative PA-6 nanocomposite material, using lignin as a graphene precursor, after going through temperature/pressure processes aiming to transform the lignin into a "lignin nanocarbon" to act as a reinforcing agent, as well as to determine the optimal formulation of PA-6/GO capable of obtaining the desired reinforcement effect for applications of these nanocomposites in structures to be used by the automotive industry.

POLYANILINE-SILICA DOPED WITH OXALIC ACID AS A NOVEL EXTRACTOR PHASE IN TF-SPME FOR DETERMINATION OF HORMONES IN URINE SAMPLES USING 96-WELL PLATE SYSTEM AND HPLC-FLD DETECTION.

Francielle Crocetta Turazzi[1], Lucas Morés[1], Eduardo Carasek[1], Guilherme Mariz de Oliveira Barra[1]

[1]Universidade Federal de Santa Catarina

e-mail: francielle.turazzi@posgrad.ufsc.br

Polyaniline (PAni) is an intrinsically conducting polymer (ICP) that has attracted much interest in different areas of science, mainly due to its unique characteristics, which include easy preparation, low cost, high stability and processability [1]. These characteristics allow researchers to easily carry out modifications of the structure by changing different synthesis parameters. This particularity gives polyaniline a wide range of technological applications, such as supercapacitor, electromagnetic shielding, gas sensor and biosensor, and it has also been used as the extractor phase for sample preparation techniques [2]. Complex samples, such as urine samples, need a sample preparation step prior to instrumental analysis and the determination of hormones in these samples is important because hormonal concentration changes in women have been associated with breast, endometrial and ovarian cancers, and they are also relevant for prenatal diagnosis [3]. The aim of this study was to evaluate the applicability of different polyanilines for the analysis of three hormones, including 17-β-estradiol (E2), 17-α-ethinylestradiol (EE2) and estrone (E1) in urine samples using the thin film solid phase microextraction (TF-SPME) technique associated with 96-well plate system and detection by high-performance liquid chromatography coupled to fluorescence detector (HPLC-FLD).

Production of air filters composed of PHBV/nanoclay fibers for enhanced indoor air quality

Lucas Gomes Rabello[1], Roberto Carlos da Conceição Ribeiro[2], Rossana Mara da Silva Moreira Thiré[1]

[1]Universidade Federal do Rio de Janeiro (*PEMM/COPPE*) , [2]Centro de Tecnologia Mineral

e-mail: lucas.g.rabello@coppe.ufrj.br

Air filters are devices designed to eliminate harmful particles from the air, enhancing indoor air quality and decreasing respiratory illnesses[1]. Poly(3-hydroxybutyrate-co-3-hydroxyvalerate) (PHBV)-based air filters can provide an environmentally friendly alternative to traditional filters composed of non-biodegradable materials since PHBV is a natural and non-toxic polyester[1]. Incorporating nanoclays into these filters can enhance their filtration capacity compared to commercial ones due to their high surface area and electrostatic charges[2]. Besides, the use of nanofiber as a potential material for composite-air filter media is a promising alternative[2]. Therefore, this work aimed to produce PHBV/nanoclay non-woven fibrous membranes for air filter applications. The filters were produced through the solution blow spinning (SBS) technique varying the polymer concentration (3-5 %m/v), bentonite clay concentration (0-0.5 %m/v), and spinning pressure (70-140 kPa). The statistical influence of the factors was assessed by analysis of variance (ANOVA). The morphology (SEM), porosity, grammage, pressure drop, and filtration efficiency of the air filters were also evaluated. The results indicated that higher PHBV concentration favored the formation of micrometric (1.7 μm) fibers, whereas spinning pressure decreased the diameter to a minimum of 0.4 μm. There was no direct statistical influence of nanoclay concentration on fibers′ diameter. The PHBV/nanoclay filter presented filtration efficiency for small airborne particles of 98% and a pressure drop of 23 Pa, which were superior properties than those of the commercial filters with higher grammage.

Recent advance in bone tissue regeneration

Mariana Ionita[1], George Mihail Valsceanu[2], Alexandra Ioana Cernencu[2]

[1]University Politehnica of Bucharest (*Faculty of Medical Engineering*) , [2]University Politehnica of Bucharest

e-mail: mariana.ionita@polimi.it

The aim of the current work is to improve the implementation of existing cell / bone substitute therapy for the serious complication of non-union bone fractures and also to provide holistic transition from conventional regenerative medicine to integrative, personalized regenerative medicine. To this purpose 3D scaffolds attractive for bone repair based on biopolymers (sodium alginate, fish gelatin, kappa-carrageenan) and graphene derivatives were fabricated and investigated under the complex condition envisaged by real-life bone repair application, e.g. biomineralization and morphological changes, structure and in vivo models. CD1 mice models were also used to assess de novo osteogenic potential by ectopic implantation in the subcutaneous dorsum pocket of the animals. The results underline the formation of mineralized extracellular matrix while specific bone markers determination stressed the osteogenic phenotype of the cells. These data support that graphene derivatives bioactivity in osteogenesis mechanisms as being self-sufficient to elevate osteoblast differentiation and bone formation in ectopic sites. Conversely, the advent of improved 3D printing technologies has enabled the engineering of bone tissue for patient-specific healing. Our aim was to develop novel printable formulations using our previous experience based on different biolopolymer e.g. gelatin/pectin polymeric matrix that integrates synergistic reinforcement effect graphene oxide and oxidized nanocellulose fibers. Using 3D printing technology and the aforementioned composite inks we fabricate bone-like scaffolds with enhanced compressive modulus, excellent printability, scaffold fidelity and high perspectives for bone tissue engineering applications. The authors acknowledge the financial support from the Ministry of National Education, Executive Unit for the Financing of Higher Education, Research, Development and Innovation (UEFISCDI), project number PCE 103/2022.

Rietveld Refinement, electrical and mechanical study of PVA/ $LiClO_4$ flexible membranes.

e-mail: yanmatheus09051997@gmail.com

Solid electrolytes have been mainly investigated in the last two decade to be applicable in battery devices. Usually, polymeric matrix blended with ionic salts results in composites, which are used aiming flexibility, stability and electrical performance, beyond being biodegradable materials[1,2]. In this work PVA (polyvinyl alcohol) blended with $LiClO_4$(lithium perchlorate) flexible membranes have been prepared, they were performed based on Solvent Casting Method. The samples were described by DMA and strain-stress measurements. They specify favorable elastic energy storage under mechanical stress. The complex impedance spectrum shows that there is a decrease in the resistance values (order of $10^3 \Omega$), up to 5% of $LiClO_4$, then, a good electrical performance. Rietveld refinement method has been done using the experimental PXRD. Is easy to see that $LiClO_4$doesn't contribute in the diffractogram profiles due to its dissociation in the synthesis samples andthe background intense decrease to 5% of lithium perchlorate, indicating an efficiency of the PVA polymerization. Therefore, we concluded that the material obtained becomes promising to keep being studied and for applications in technological devices.

Self-Healing and Electrical Behavior of Reduced Graphene Oxide-Doped PEI/PAA LbL Films

Shirley Monteiro Vieira da Rocha Hossack[1], Antonio Riul Jr.[1], Varlei Rodrigues[1]

[1]Universidade Estadual de Campinas (*Departamento de Física Aplicada*)

e-mail: smvr.hossack@gmail.com

Developing new materials for organic electronics is essential for advancing technology in fields such as soft robotics, biomedical devices, and sensors. Self-healing materials with good electrical transport properties are highly desirable for all these applications, which can be achieved by forming nanocomposites. This study explores the self-healing and electrical behavior of a polymer matrix doped with reduced graphene oxide (rGO) nanoplates. The matrix film is obtained by the layer-by-layer (LbL) deposition of poly(ethyleneimine) (PEI), poly(acrylic acid) (PAA), and functionalized rGOs. Impedance magnitude curve is acquired for each layer deposited during the LbL film assembly and I vs V curve after deposition. The high water affinity of the PEI/PAA matrix strongly influences the electrical behavior of the composites, which we investigated by conducting experiments at different humidity levels. The I vs V measurements were acquired in three potential ranges with sweep cycles ranging from -V to +V, for V = 2, 3 and 5V in two distinct voltage steps, indicating hysteresis. We observe that the current increases in each voltage cycle, suggesting the presence of charge carrier traps that could be used to form a memristor. Overall, our findings provide insights into the properties of reduced graphene oxide-doped polymer matrices, with potential applications in the development of self-healing organic electronics.

e-mail: ricardo.andrade@mackenzie.br

In this study, 0.1 wt.% of graphene nanoplatelets (GNP) or 0.1 wt% of multilayers graphene oxide (mGO) are incorporated into TPU matrix using solution casting processing, and the contribution on the phase separation of these domains is observed. This phenomenon is even more pronounced when graphene-based nanocomposites are submitted to annealing at 110 ºC for 24 hours, suggesting a good interaction between the GO and GNP with the hard and soft segments, respectively. After annealing, the nanocomposites present better performance in shape memory effect regarding the increase on shape recovery ratio (Rrec) of around 9% compared to the non-annealed TPU. All nanocomposites maintained a high strain during SME programming, higher than that of the pure TPU, before and after annealing, indicating a direct influence of the graphene on the shape memory effect.

e-mail: a165060@dac.unicamp.br

This work presents two projects using natural fibers and polymer matrix composites that consider the impact of the materials used in the communities and the environment. The first project focuses on the design and manufacturing of an urban bicycle frame with a recyclable PET core material reinforced with banana fiber and castor oil polymer matrix. The second project explores the design of a prosthesis for para-athletes with a sisal fiber reinforcement and epoxy matrix. The paper discusses the rationale behind the selection of the design using geometric and parametric optimizations, the properties of the fiber and composite laminate found in the literature, the manufacturing process using Resin Transfer Molding (RTM), and the feasibility and scalability of the product. A prototype of the bicycle and the prosthesis were built to compare the fully handmade process with an industrial process with greater resources. The paper shows experimental test data and comparison with the simulated performance from the design phase. The results show that despite the challenge in manufacturing composite structures with such unconventional materials, the solutions presented structural integrity within a predictable range. These results are a significant step towards the use of natural fiber composites as a socially and environmentally sustainable alternative to more classical synthetic composites.

The impact of carbon nanoparticle dispersion and concentration on IPN-based nanocomposites' properties

Matheus Mendes de Oliveira[1], Danilo Justino Carastan[1]

[1]Universidade Federal do ABC

e-mail: matheus.mendes@ufabc.edu.br

Conductive polymer coatings are in high demand due to their versatile properties. They are especially interesting for the airspace industry, which could employ them as lighter electromagnetic shielding and lightning strike protection devices for modern aircraft frames 1. Graphene and related nanomaterials, such as CNTs, have been extensively employed in the fabrication of conductive polymer materials. Adding them to a homogeneous polymer matrix is the most common approach, but using immiscible polymer blends can lead to much lower percolation thresholds due to the double percolation phenomenon: by selectively dispersing the nanofillers into a minor continuous phase or placing them at the interface between two co-continuous phases, their concentration can be locally increased 3. Within this framework, interpenetrating polymer networks (IPNs) are a class of polymeric systems composed of two or more immiscible polymers with no covalent bonds between their chains and that are interlocked on a molecular scale. Poly(ether imide) (PEI) is typically used in combination with epoxy resins to form IPNs, resulting in a biphasic morphology split between epoxy- and PEI-rich phases 3. This morphology not only leads to better mechanical and thermal properties but also allows for double percolation phenomenon to take place. The addition of GNPs and CNTs in IPN systems have not been widely studied in literature,and the dispersion aspect of the sample fabrication has been largely ignored. By comparing ultrasonic- and mechanical-based dispersion routes, we have established the best approach for fabricating carbon nanoparticle-reinforced epoxy/PEI IPN nanocomposites and investigated their electrical and mechanical properties.

The Role of Carbon Nanotubes Dispersion in PVDF/CNT Electrospun Nanofibers

Maurício Marquevicz Kubaski[1], Étienne Beaudoin[1], Nicole Raymonde Demarquette[1], Ricardo J Zednik[1]

[1]École de Technologie Superieure (*Génie Mécanique*)

e-mail: mauricio.kubaski.1@ens.etsmtl.ca

Conductive electrospun fibers are made using conductive nanofillers, such as carbon nanotubes (CNTs), carbon black or graphene mixed with a spinnable polymer [1,2]. However, the nanofiller agglomerates interfere on the spinnability, consequently the fiber quality and its electrical conductivity. This is a challenge in order to produce suitable flexible electronic devices. Thus, in this project we studied the incorporation of carbon nanotubes (CNTs) in polyvinylidene fluoride (PVDF) nanofibers using electrospinning in order to form an electrically conductive structure [3]. PVDF and CNT were dissolved and dispersed to obtain an electrospinnable solution of dimethylformamide (DMF) and acetone. This mixture was then electrospun using a drum collector in order to produce the aligned nanofibers. The CNTs percolate to form a conductive network resulting in electrically conductive nanofibers. The percolation threshold was found to be time-dependent. The time-dependency of the percolation threshold shows that a lower CNT concentration can be used to achieve electrical percolation while avoiding agglomeration, thereby helping to manufacture electric devices that require conductive nanofibers. As the percolation depends on both concentration and dispersion time, the rheological properties must be well understood in order to achieve the desired material properties.

4D Printing of Thermoresponsive Hydrogels

Diego Moreira Lima[1], Mathilde Champeau[1], Anne Cristine Chinellato[1]

[1]Universidade Federal do ABC

e-mail: diego.moreira@ufabc.edu.br

Printable 4D materials dynamically change their shape in response to external stimuli, such as temperature, pH, or light. As a result, it has the potential to enable the development of smart materials and self-assembly systems for various applications [1]. Poly(N-isopropylacrylamide) (PNIPAm) is a promising hydrogel for 4D printing, as it undergoes reversible volumetric chances in response to temperature. This thermoresponsive behavior allows the material to adapt to environmental fluctuations and can be used to create structures with controlled geometries. Alas, the poor mechanical strength of PNIPAm can hinder its application for printing. To bypass this problem, one can develop double network systems, although these modifications could potentially impact the thermal-responsivity of PNIPAm. The addition of inorganic compounds, such as boron nitride nanostructures, could minimize the impact on the thermoresponsiveness. Boron nitride nanosheets (BNNS) are 2D materials that can be incorporated in hydrogels to improve its overall properties [2]. It exhibits biocompatibility, excellent mechanical strength, chemical stability, and high thermal conductivity. As the thermal response is related to the polymers' thermal conductivity, it is expected that the BNNS could modify this property. Thus, this work evaluates the influence of the BNNS on the thermal responsiveness of the printable nanocomposites. Functionalized BNNS were incorporated into fixed content hydrogels at different concentrations, and their distribution within the matrix was analyzed using SEM. FTIR was used to evaluate the chemical structure, and DSC was employed to visualize thermal events.

Anionic block amphiphilic copolymer synthesis by RAFT for the generation of antimicrobial particles

Everton Leandro Santos Amaral[1], Fabio Herbst Florenzano[2], Igor Wallace Ferreira da Silva[3]

[1]Escola de Engenharia de Lorena da Univerdade de São Paulo, [2]Escola de Engenharia de Lorena - Universidade de São Paulo (*Departamento de Engenharia de Materiais*) , [3]Monash University

e-mail: evertonlsa@usp.br

The synthesis of block polymers the combination of different repetitive units for the planning and control of characteristics such as molecular weight and chain architecture, enabling new studies and the creation of unprecedented polymeric materials for a variety of applications [1]. In this work, we report the syntheses by RAFT of amphiphilic block copolymers the oriented towards the generation of antimicrobial systems. All syntheses were monitored by GPC and characterized by FTIR. The aggregation of the final amphiphilic materials in aqueous media was analyzed by DLS. The syntheses were performed in two steps. Firstly, the macroCTA of PS was obtained followed by the second block of PtBA. The PS-b-PtBA copolymers were hydrolyzed to provide the amphiphilic PS-b-PAA. GPC monitoring indicated that reactions have occurred in a controlled manner. Characterization by FTIR confirmed the chemical structure of the materials. In pH 7 aqueous solution, copolymers aggregated into particles presenting average hydrodynamic diameter of hundreds of nanometers 345 ± 31 nm by DLS. It has been shown that the method based on RAFT was able to generate designed amphiphilic block copolymers with systematic changes on the molar mass and composition. The PS-b-PAA copolymers, with different ratios between the blocks content, will be subsequently tested for their antimicrobial action, whether or not bound to copper cations or others.

Anticrusting membranes of polyurethane with zirconia nanoparticles

Marla Almeida Siqueira[1], Cleocir Jose Dalmaschio[2]

[1]UNIVERSIDADE FEDERAL DO ESPÍRITO SANTO (*Departamento de Química*) ,
[2]Universidade Federal do Espírito Santo (*Departamento de química*)

e-mail: MARLAAS@HOTMAIL.COM

Industrial oily wastewater and oil spills have a negative impact on the environment and human health, attracting attention in development of new technologies. In this study, polyurethane (PU) membranes were produced using the phase inversion technique, for pure polymer and additive with zirconia nanoparticles (NPs) incorporated into the polymeric matrix. The surface of the NPs were functionalized with oleic acid. The incorporated NPs were characterized in terms of crystallinity, particle size, and surface functionalization. The membranes were structure characterized by microscopy and the permeability using aqueous fluid. The crystalline and particle size characterizations revealed that the NPs have a monoclinic crystal phase and an average particle size of 6 nm. Microscopy images revealed that the incorporation of NPs in membranes results in porosity controlled by additive. Permeability tests indicated that the incorporation of NPs reduced membrane permeability, but with a steady flow, indicating that the NPs content change membranes structure, preventing compaction compared membrane without NPs additive. The results suggest that membrane porosity can be altered through phase inversion, with NPs incorporation being key to obtaining resistant and efficient separation membranes. Therefore, this study demonstrates the potential of adapting the PU matrix with oxide NPs membranes for use in emulsion separation processes.

e-mail: renato_rqa@hotmail.com

Films obtained from renewable and biodegradable biopolymers, such as cassava starch, have received great attention related to their environmental impacts and use in the food packaging industry. In this study, active biodegradable cassava starch films with antioxidant capacity through the incorporation of buriti oil were produced. The films were developed using the casting technique (4 g of starch/100 mL of water) with the addition of glycerol asa plasticizing agent (0.25 g of glycerol/g of starch), the active compound was incorporatedat concentrations of 5% and 10% [1]. The films were characterized for barrier properties (moisture content, water solubility, water vapor permeability and light transmission) [2]. The results confirmed that the addition of buriti oil modified the properties, obtaining films with greater color intensity, better barrier to light transmission, and reduced permeability to water vapor. This behavior is associated with the hydrophobic nature of the active compound incorporated into the polymeric matrix, as well as the presence of natural antioxidants in the oil, such as carotenoids. A reduction in the moisture content and water solubility was also observed, which favors a greater application of these materials as packaging for different food matrices.

e-mail: renato_rqa@hotmail.com

The development of films from biopolymers has been studied to replace or reduce the use of synthetic polymers and conventional plastic packaging, associated with the interest in increasing food stability from the addition of bioactive compounds to the polymeric matrix. In this context, cellulose acetate was used to produce active films with different concentrations of pequi oil (5% and 10%). The films were obtained from the technique and the effect of oil incorporation on barrier properties was evaluated [1,2]. According to the concentration of added oil, there was a gradual increase in the color intensity of the films, associated with the presence of carotenoids (such as β-carotene), with a significant reduction in UV-Vis light transmission. There was an increase in the opacity of the films, of 0.33 ± 0.03 Abs600nm/mm, 2.18 ± 0.02 Abs600nm /mm, and 2.85 ± 0.05 Abs600nm /mm, for the control film and films with 5% or 10% oil, respectively. As expected, the hydrophobic character of the oil led to a reduction in water vapor permeability, from 0.32 ± 0.02 g mm m-2h-1 kPa-1 to 0.12 ± 0.02 g mm m-2h-1 kPa-1, for the control film and the film withthe highest concentration of antioxidant additive. Pequi oil can be an additive used to obtain biodegradable packaging with antioxidant capacity and a better barrier to the light transmission, which demonstrates the potential stability of foods susceptible to photodegradation.

Biopolymeric films loaded with hybrid nanoplatforms based on Carbon Polymer Dots and Halloysite

Rebecca Jemima Pereira Araujo[1], Elaine Sá Menezes Cutrim[1], Ana Clécia Santos de Alcântara[1]

[1]Universidade Federal do Maranhão

e-mail: jemima.rebecca@discente.ufma.br

Carbon polymer dots (CPD) are a novel type of fluorescent, carbon-based nanomaterial (0D) with a of less than 20 nm. Due to their unique properties, CPD have potential applications in various fields of interest, such as optical, electronics, sensors, or biomedicine [1]. On the other hand, another promising material is clay minerals, which can be combined with diverse species and form composites with low toxicity, increased biocompatibility, and improved mechanical stability [2]. Within this perspective, clay minerals can also be combined with polymers which can be processed as functional composite films. In this study, alginate (A) and carboxymethylcellulose (CMC) polysaccharides blend was combined with a hybrid material developed by the union of Halloysite clay mineral (HC) and CPD at different concentrations to form reinforced biodegradable films. The films were characterized by diverse physicochemical techniques, and their barrier and mechanical properties were investigated. The FTIR spectra of the films indicated strong hydrogen bonds between the components of the material, at the same time that the introduction of hybrids into the biopolymeric matrix significantly blocked a substantial portion of the UV radiation due to the ability of the CPD to absorb ultraviolet radiation and blue photons [3]. In addition to good mechanical properties, the water vapor transmission rate of the resulting films showed a decrease of almost 2 times in the composite films compared to the pure polymer film, indicating that the addition of HC-CPD hybrid improved the barrier properties against water vapor.

Carboximethylchitosan/*Jatropha mollissima* compoundfor hemostatic application

Dayanna Kelly Marques de Oliveira[1,2], Wladymyr Jefferson Bacalhau de Sousa[3], Marcus Vinicius Lia Fook[3]

[1]Universidade Federal de Campina Grande (*DEPARTAMENTO DE CIÊNCIAS E ENGENHARIA DE MATERIAIS*) , [2]Universidade Federal de Pernambuco (*DEPARTAMENTO DE CIÊNCIA DOS MATERIAIS*) , [3]Universidade Federal de Campina Grande (*DEPARTAMENTO DE CIÊNCIA E ENGENHARIA DE MATERIAIS*)

e-mail: dayanna.moliveira@ufpe.br

Traumatic injury is responsible for more than 5.8 million deaths/year, although there are considerable advances in the area of hemostatics, blood loss is one of the biggest causes of death in hospitals. The development of optimized hemostatic agents can be an alternative to minimize this problem, as is the case of the biomaterial based on O - carboxymethyl chitosan with the addition of Jatropha mollissima, objective of this work. The o-carboxymethylchitosan was synthed from chitosan and later, the nanoparticles were obtained by the ionic crosslinking method. The ethanolic extract of the sap was obtained by the ionotropic gelation technique. The O - carboxymethyl chitosan solution was obtained ata concentration (0.25 m/v), added with 1.25% (m/v) of the ethanolic extract of jatropha mollissima sap. The raw material was characterized by Fourier Transform Infrared Spectroscopy (FTIR) and Solubility. The nanoparticles were characterized by Dynamic Light Scattering (DLS); Zeta potential (PZ), UV-vis and hemostatic activity. In the FTIR, it was possible to observe the formation of characteristic groups present in O - carboxymethyl chitosan, in the ethanol extract of the sap, the presence of groups related to flavonoids, terpenes and amino acids was observed. In the evaluation of the solubility, both of the carboxymethylchitosan and the extract, it was observed that both are soluble in water. In the DLS, it was found that the nanoparticles present homogeneity and an average of 265.24 ± 2.30. In PZ, the nanoparticles suspension showed an average instability of -16.77 nm, which is desirable for application as hemostatic for stabilizing bleeding. In UV-vis, the encapsulation rate had an efficiency of 12.5%, which did not interfere with the hemostatic effectiveness in vivo. Based on the results, it can be concluded that it is possible to obtain nanoparticles of O - carboxymethylchitosan/jatropha mollissima with potential for use as a hemostatic agent.

CHARACTERIZATION OF A NEW POZZOLANIC BINDING INGREDIENT ORIGINATED FROM THE MIXTURE OF CLAY AND SUGAR CANE LEAF.

e-mail: gean.jr@unesp.br

Portland cement is one of the most widely used materials in the construction industry, but its production is highly associated with greenhouse gas emissions, raising environmental concerns and pressures for sustainable alternatives. In this context, the use of agro-industrial waste such as sugarcane leaves has been proposed as a viable solution for the production of alternative binders. This study presents a new pozzolanic binder obtained by combining sugarcane leaves and clay (CFCA), in which the former is used as fuel in the calcination process, integrating these two pozzolanic sources and providing satisfactory benefits. CFCA was subjected to grinding and sieving processes. Mortars were produced with partial substitutions of Portland cement by CFCA in different proportions (control, 10%, 20%, 30%, 40%, and 50% by weight), evaluating the consistency, which reduces as the substitution increases. The mechanical strength of the mortars before and after exposure to fire at a temperature of 600°C for two hours resulted in a decrease in compressive strengthin the increasing order of Portland cement substitution by CFCA, being from 35% to 43%. However, even with this reduction, the results still indicated that it is possible to substitute Portland cement with CFCA up to 50% by weight, resulting in approximately 23 MPa after exposure to fire, showing that the use of CFCA can be a promising and sustainable alternative in the production of binders for the construction industry.

The developing of bioactive scaffolds to bone repair has been an alternative, but suffers from limitations regarding the extent of bone loss and the morbidity of the donor site [1]. Poly(ε-caprolactone) (PCL) has good biocompatibility and biodegradability, suitable for making bone scaffolds. However, its smooth surface and strong hydrophobicity generate low biological activity, not being viable for adhesion of osteoblasts and regeneration of bone tissue when used alone, requiring the addition of materials that corroborate the desired cellular viability.[2][3]. In the present work, rotary jet spun PCL/Chondroitin Sulfate containing different concentrations of lyophilized bone powder were produced for biomedical applications. So far, morphological and chemical characteristics have been evaluated. For the next steps, mechanical tests, in vitro and in vivo, will be performed, in addition to other characterizations to check the properties of each group. After that, all other results will be analyzed, in order to verify the functionality of the material and applicability in Bone Tissue Engineering.

Characterization strategies to investigate ionizing radiation effect on nanocarbon material

Maria Cecília Conceição Evora[1], Odair Lelis Gonçalez[1], Willians Principe Fernandes[2] [1]Institute of Advanced Studies (*Nuclear Energy Department*) , [2]Institute of Advanced Studies (*Nuclear Energy Department*)

e-mail: evoramac@hotmail.com

Advanced carbon-based materials, such as carbon fibers and other nanostructured forms of sp^2carbon, will enable revolutionary applications, as long as one can promote good dispersion in substrates and matrices. Electron beam irradiation can induce structural modifications leading to point of defects, voids and/or displacements and establish active sites to attach desired functional groups to improve this dispersion. The energy threshold for incident and tangential electrons capable of creating these changes is 15 eV to 22 eV and 33 eV to 44 eV, respectively [1]. Despite this complexity, this work will present results of characterization techniques that can help to evaluate the effect of ionizing radiation on carbon nanofiber structure. TGA, XRD and XPS techniques were used to assess the modification on carbon nanofiber (CNF) structure when submitted to direct radiation grafting process. TGA results showed that this process in solution of acrylonitrile (AN) 40% v/v obtained a high yield of nitrogen grafted on CNF surface, which is in accordance with XPS results. Direct radiation grafting of CNF in solution of 40, 60 and 80% v/v of AN presented nitrogen content of 13.5%, 10.2% and 7.2%, respectively. There is also clear indication that the sp^2-type carbon is being disrupted, showed by the reduction of sp^2/sp^3rate from 8.93 to 0.76 for CNF immersed in AN solution not irradiated compared to the irradiated one at same conditions.

Acknowledgments: We would like to thanks Kulun Hong of Oak Ridge National Laboratory for the XPS results and Dr. Roberto Uribe of Kent State University for the radiation experiments.

e-mail: fr.rodrigues@unesp.br

Recently, several works have been carried out with the use of rice hull ash (RHA)in the production of concrete, and a lot of self-compact concrete (SCC) has been produced. However, with this objective, concretes were produced with the use of RHA, but this material is industrialized, in the content of 35% in relation to the cement in addition, was varied and the relationship "water/cement" ; in relation to the "superplasticizer/cement" with was constant. Two series of vibrated concrete were also produced, for comparative purposes, one varying the "water/cement" ratio by 0,4; 0,5 and 0,6 and keeping the relationship "coarse aggregate/total mass of concrete" and another one keeping the relationship "water/cement" at 0,5 and varying the relationship "coarse aggregate/totalmass of concrete" . Note that the RHA was suitable for manufacturing the SCC, so that theymet the requirements in the fresh state, and in the weathered state. Validation tests werecarried out for the SCCs in the fresh state, Slump-Flow, V-Funnel, and the Case L [1], segregation tests by sieving, and the evaluation of the apparent dry specific mass. Both forcases of SCC and for cases of vibrated concrete, tests were carried out in the state of resistance, simple resistance, diametral resistance, modulus of elasticity, water absorption tests at 28 days of curing. The SCC mechanical strength values remained higher, despite thehigher values for the "water/cement" relationship, and the mechanical strength values relative to the absorption values remained more consistent for SCC. Also-note that self- compacting concretes showed signs of greater ductility than vibrated concretes.

e-mail: victor_vencao@hotmail.com

In civil construction, several types of materials are used in the works, such as cement. However, it has factors that compromise the application and lead to undesirable pathologies in constructions. Therefore, to improve the performance of these materials, several studies aim to improve Portland cement with the addition of cellulose microfibers, which is a type of renewable and sustainable resource. With this, it can improve the quality of mechanical properties and durability, making it possible to make buildings more efficient. In this way, this study aims to carry out a previous research of the mechanical properties of Portland cement mortars and cementitious composites reinforced with cellulose in civil construction, so that the benefits can be seen and analyzed and where this new technique can be improved to assist in the construction. As a Narrative Literature Review study, this work brought an exploratory study, based on articles published from 2003 to 2022. Use of descriptors to delimit the research fields and mortar: Portland cement, composite, cellulose, mechanical property. The following databases were used: Scopus, Web of Science; Scielo, ScienceDirect and Google Scholar. It can be concluded after analyzing all the articles chosen that the use of cellulose in mortars has positive effects on the mechanical and microstructural properties of the materials when used in adequate amounts, as in addition to being a biodegradable and ecologically correct material, it improves resistance to compression, has a higher modulus of elasticity, greater tenacity and durability and resistance to mortar cracking. However, there are still challenges to be overcome.

Compositional evaluation associated with the electrical and electrochemical performance on Ni-modified silicon oxycarbide (SiOC/Ni) ceramics

Alexandre Costa Guimarães Cruz[1], Alexandre Urbano[2], Daniela Martins Fernandes de Oliveira[3], César Ricardo Teixeira Tarley[1,4], Mariana Gava Segatelli[1]

e-mail: alexandrecosta.guimaraescruz@gmail.com

Silicon oxycarbide (SiOC) matrices are structurally modified through incorporation of transition metals to polymer precursors, improved formation of electroactive phases (graphitic domains and SiC) when electrical applications are required[1]. This study evaluated different amounts of nickel chloride at the Ni-containing SiOC materials, aiming electrical and electrochemical investigations. Six polymers were synthed by reaction between 60 wt.% poly(methylhydrosiloxane) and 40 wt.% divinylbenzene, containing 20 wt.% polyethylene and addition of 0,1,3,5,10 and 20 wt.% of $NiCl_2$. Ceramics were obtained at 1400 °C under static argon atmosphere with heating/cooling rate of 5 °C/min. FT-IR spectra for SiOC/Ni ceramics revealed three typical bands attributed to νSi-O-Si, νSi-C and δSi-O, confirming the mineralization process. The larger amount of nickel allowed the replacement of oxygen by carbon atoms. Static argon atmosphere combined with greater amounts of $NiCl_2$resulted in a proportional increase of graphitized ceramic. The proportionof β-SiC phase increased up to 5 wt.% Ni and decreased for ceramics with 10 and 20 wt.%. The length of carbon crystallites in-plane increased up to the SiOC 5% nickel and reductionsfor those with 10% and 20%. The resistivity on the powdered ceramics showed promisingalternative as conductive material. The highest and lowest resistivity values were 129.88and 0.44 Ωcm, corresponding to Ni-free SiOC and 5 wt.% Ni SiOC, respectively, so 10 and20 wt.% Ni SiOC showed resistivity of 1.38 Ωcm. Resistivity values depend on thecombination of β-SiC and graphite phases not exclusively on a single conductive phase, arising from different proportions of nickel in a static atmosphere. Furthermore, SiOC/Ni presented larger electroactive area values when compared to glassy carbon electrode,whichbecame promising for development of electrochemical devices.

e-mail: rayssalopes@estudante.ufscar.br

Polyvinyl alcohol (PVA) is a water-soluble synthetic polymer, has interesting mechanical and thermal properties, in addition to being biodegradable and non-toxic1, while polyaniline (PAni) is a conductive polymer sensitive to external stimuli such as light, humidity and pH . The addition of PAni to PVA can increase its electrical conductivity and thermal stability, maintaining its solubility in water, making it useful in the production of flexible electronic materials. The modification of PAni with dodecylbenzenesulfonic acid (DBSA) is a common process that aims to improve the solubility, stability and mechanical properties of the conductive polymer2. The copolymerization of PVA with DBSA-modified PAni can be accomplished in a number of ways, including mixing solutions of the two polymers followed by solvent evaporation. The double-distilled aniline was quickly added to a solution of (NH4)S2O8 solubilized in a 1.00 mol.L-1 HCl solution, the proportion of oxidizing agent:monomer used was 4:1 (n:n). The solution was stirred for 3 hours in an ice bath. The emeraldine salt obtained was placed under strong agitation in a solution of NH4OH 0.1 mol.L-1 for 24 hours, after which the base was filtered under vacuum, washed with distilled water and dried in an oven at 60°C for 48 hours. The heavy base was solubilized in DBSA ata 70:30 (m/m) dopant:polymer ratio. The mixture was left stirring for 48 hours2. To obtainthe composites, PAni-DBSA in proportions 1, 3 and 5% were added to a 10% PVA solution,under stirring for 4h. The presence of functional groups and identification of the chemicalbonds formed were observed using Infrared absorption spectroscopy. The morphological structures of the films were observed using scanning electron microscopy (SEM), the thermal analyzes were analyzed using thermogravimetric analysis (TGA). The electrical properties were characterized by means of electrical conductivity measurements.

Conformational analysis of ionic liquids through residual dipolar couplings probed through polymeric gels as an alignment medium

Higor Diego Farias de Melo[1], Fernando Hallwass[2], Armando Navarro-Vázquez[2]

[1]Universidade Federal de Pernambuco (*Ciência dos materiais*), [2]Universidade Federal de Pernambuco (*DQF*)

e-mail: higordfmelo@gmail.com

NMR in weakly aligned media allows the precise extraction of anisotropic NMR parameters that can then be applied to configurational, conformational or even constitutional structural problems. Among the many alignment media available today, reversibly compressible polymer gels such as chemically cross-linked PMMA[1] or polyacrylonitrile[2] allow particularly easy measurement of not only residual dipole couplings (RDCs) but also residual chemical shift anisotropies (RCSAs). Here we present new crosslinked copolymeric gels that can be swellable in common ionic liquids such as BMIM·NTf2- or BMIM·BF4-. The new developed gels allow the extraction of 1DCH RDCs in the butylmethylimidazolium cation and the determination of their conformational space in the pure liquid. The results were in line with previous reports based on Raman spectroscopy.[3] Additionally, the analysis of the 1DCH couplings in the planar imidazolium ring allowed the assignment of the H4/H5 positions of the ring.

Development of Biodegradable Active Packaging Containing Chia Seed (Salvia Hispanica L.) Extract Nanoparticles with Antioxidant Function

Mariana da Silva Alves[1], Maria Inês Bruno Tavares[1]

[1]Universidade Federal do Rio de Janeiro (*Instituto de Macromoléculas Professora Eloisa Mano*)

e-mail: marianaalves_21@hotmail.com

From data analysis about food conservation, waste, illness from consuming globally contaminated food [1], and incorrect packaging disposal, the need for the development of biodegradable food packaging that increases the shelf life of food and promotes quality assurance is observed [2]. Therefore, the development of active packaging not only protects the food against mechanical factors but also promotes quality and protection against common chemical factors, such as lipid oxidation in food. The use of biodegradable polymers has been studied in recent years, as it is an area with great potential for development not only in packaging but also in various other sectors. The food packaging industry has been using additives, usually synthetic ones, which not only encase the food but also promote an increase in its shelf life, thus prolonging the time it can be stored and reducing food waste [3]. Therefore, this study aims to develop an active packaging with a biodegradable polymer (polycaprolactone - PCL) containing chia seed extract nanoparticles, due to their high antioxidant potential in their composition, with the function of preventing food oxidation. This film was produced with PCL and the nanoparticles were produced through the nanoprecipitation technique. The formed film was characterized regarding the of the nanoparticles, stability in 30 and 60 days, as well as its antioxidant function, obtaining satisfactory results for its initial application.

Acknowledgments: CAPES - Funding Institution.

e-mail: pg404263@uem.br

Polyurethane is a versatile material widely used in various industries, such as construction, automotive, furniture, and footwear. It is characterized by its strength, durability, flexibility, and lightness, as well as being an excellent thermal and acoustic insulator, especially in the form of polyurethane foams (PF). However, PF disposal presents challenges, as they take about 30 years to start degrading and release carbon monoxide when burned. This study aims to explore the effect of substituting polyethylene glycol (PEG), the main polyol in PF composition, with natural fibers from guarana bagasse, and to investigate the incorporation of antimicrobial agents in the foams, comparing two substances with distinct antimicrobial properties: silver nanoparticles (AgNPs) and nano-chitosan (NC). Two distinct methodologies were applied to determine the best combination of fiber and polymeric matrix, differing in the order of reagent addition in the reaction. In synthesis 1 (S1), the fiber was homogenized before adding the other reagent in synthesis 2 (S2), the fiber was added along with the last reagent. For the foam synthesis, guarana bagasse fibers were used, including in natura fibers (NF) and treated fibers (FT) with sodium hydroxide. The substitution of PEG by guarana fibers varied from 5% up to a maximum limit of 30% for PF formation. Foams obtained by methodology S1 exhibited greater homogeneity in their structure compared to those produced by S2. When analyzing the ash content in different parts of the S2 foams, variations in values were observed, suggesting a non-uniform distribution of guarana fibers in the polymeric matrix. Mechanical tests showed promising results, indicating that the partial substitution of PEG by natural fibers from guarana bagasse in PF synthesis and the addition of antimicrobial agents, such as AgNPs and NC, are viable solutions.

Diffusion of chlorides in mortars composed withbamboo leaf ash

Lucas Henrique Pereira Silva[1], Miguel Angel de la Rubia Lopez[2], Jacqueline Roberta Tamashiro[1], Fábio Friol Paiva[1], Angela Kinoshita[1], Amparo Moragues Terrades[2]

e-mail: lucashpsilva@ifsp.edu.br

Durability of structures is a constant concern in civil and materials engineering, especially when they are exposed to aggressive environments. In buildings with a concrete structure, durability is profoundly reduced when harmful agents penetrate through the pores of the cementitious composite and alter the microstructure and properties of the materials. The attack by chloride ions leads to severe deterioration of reinforced concrete structures, being cited as the most common mechanism of degradation of these structures [1]. The search for new pozzolanic materials is emerging in view of the need for more sustainable binders and, for this purpose, bamboo leaf ash has been identified as an excellent partial substitute for cement. In the development of new materials, accelerated tests represent a good alternative to reduce time and expenses in material evaluation. In order to evaluate the migration resistance of chlorides in composites mortars with 0, 20, 25 and 30% BLA replacing cement were produced and the accelerated method recommended by NT BUILD 492 was carried out. The migration coefficients in the respective mortars were 11.8, 4.53, 4.72 and 6.07. Mortars with CFB showed much higher resistance to chloride penetration than the reference mortar, especially the mortar with 20% replacement. Other durability tests must be conducted, however, this result indicates that the BLA is a is very promising pozzolanic material that allows to obtain cement based materials more sustainable materials decreasing CO2 footprint and with very good durable behavior against chloride penetration.

e-mail: ingrid_vfmonteiro@hotmail.com

In agriculture, nanosystems used as bioinsecticides, such as polymeric nanocomposites, have been successfully used in insect-pest management. When promoting the encapsulationof biological agents, such as entomopathogenic fungi, the objective is to preserve the inherent characteristics of the active agent. Nanocomposites containing alginate(biopolymer) and different concentrations of bentonite (lamellar silicate) exert a barrier effect responsible for modifying the release of the fungus, giving it protection [1]. Thus, beads-type encapsulation matrices of the entomopathogenic fungus *Beauveria bassiana* composed of alginate (1%) and bentonite (2, 4 and 6%), were obtained by ionotropic gelation and dried by air flow or freeze-drying, through fast and slow freezing.The formulations were characterized by: XRPD and FTIR, average particle size, intumescence index and in vitro release. The increase in the concentration of lamellar silicate conferred improvements to the mechanical properties of the beads, ensuring the preservation of the bioactive in formulations submitted to freeze-drying. With this, the preparations with concentrations of 4 and 6% of bentonite and dried by airflow stood out,showing promise in the development of a solid formulation of the bioinsecticide.

Since the advent of solid-state batteries many materials have been used as electrolytes to get better ionic conduction through its crystalline structure. Some types of polymers are interesting to be used in battery components because they combine high mobility of charge carriers and flexibility [1]. For this purpose, in recent years, composites with lithium salt have been use achieving a significance increase in the electrical properties [2,3]. In this work, flexible composites have been prepared, PVA (polyvinyl alcohol) blended with LiOH (lithium hydroxide monohydrate) in the following proportions, 0, 5, 7 and 9% in weight. It was prepared via Solvent Casting Method. As results, X-ray diffraction patterns shows the reflections of monoclinic unit cells of PVA and the increase of the crystallinity due the ion Lithium adsorption, while DFT study reveals changes of charge and atoms distances between $Li^+$and oxygen. The complex impedance spectrum indicated that there is a decrease in the resistance values of the composites up to 7% of LiOH reaching a solubilitylimit. Therefore, we concluded that the material obtained becomes promising for applications in technological devices.

Conjugated polymers are a class of materials that have attracted considerable attention in terms of research and development of new materials. In this context, a recent concept has been proposed for the application of these materials in the development of fingerprints on metallic surfaces, which is of great forensic interest due to the low success rate in the development through conventional methods. This method is based on the insulating characteristic of the sebaceous residue of the fingerprint. The use of electrochemistry makes it possible to manipulate properties and thickness of the conducting polymer films asa function of the applied electrical potential, allowing the adjustment of the visual contrast between the fingerprint and the metal surface [1,2]. Polypyrrole films were electrodeposited on stainless steel surfaces containing latent fingerprints from monomer solutions in aqueous medium, to obtain polymer films with different thicknesses. Electrochemical deposition was performed using a three-electrode system, through different electrochemical techniques in which the experimental conditions (current or electric potential applied, time of application and concentration of the solutions) were varied. The images obtained after the development of the fingerprints were analyzed using the Griaule Forensic Fingerprint software version 1.1, where it was possible to verify the characteristics of a fingerprint such as singular points (core and deltas) and individualizing minutiae (morphology, continuity of ridges, distortions and pores). Therefore, the results of the analysis showed that the images obtained are of high quality for forensic examinations and attend the requirements for the application of technical procedures for human identification.

Langmuir and Langmuir-Blodgett (LB) films were fabricated from epicuticular wax, that had been extracted from Vitis vinifera. For Langmuir films, the influence of subphase temperature on their structure was examined, whereas for LB films, the surface morphology at various temperatures and the effect of the layer number on electrowetting were investigated. Isotherms of surface pressure revealed no well-defined phase transition or collapse on Langmuir films at 22 °C, whereas Brewster angle microscopy showed that even before starting the compression procedure, there are platelets of epicuticular wax floating on the subphase. Those platelets give rise to the Langmuir films of epicuticular wax during compression. In contrast, for higher temperatures (40 °C and 50 °C), a well-defined phase transition was found - without epicuticular wax platelets, with a behavior close to those found in typical fatty acids. For LB films, atomic force microscopy images indicated a decreasing of roughness as a function of the subphase temperature as a result of greater organization of the epicuticular wax film. A significant modulation of about 20 ° (under applied voltage range of 0 to 100 V) was demonstrated of the electrowetting on LB films, which did not depend on the LB layer number. Our results suggest that epicuticular wax LB films have the potential for being applied in electrowetting-based devices. Furthermore, the Langmuir-Blodgett technique is feasible to fabricate films with various compositions focusing on the electrowetting.

e-mail: paulo_dyer@yahoo.com

Composite materials, based on asphaltic binder (AB) and mineral aggregates (MA); aka hot-mix asphalt (HMA); has a worldwide applicability in road infrastructures. However, the currently sustainable development concerns requires sustainable solutions employed on these project considering its high demand of natural resources. In this perspective, the waste foundry sand (WFS) becomes an alternative, due to its high production by foundries and MA similarity. Thus, this paper presents an evaluation on HMA containing 50% of WFS replacing the MA (in weight); according to mechanical, microstructural and chemical properties correlation. The results shown similarity to structural aspects of conventional HMA and within the road engineering international criteria; indicating the technical viability of WFS use. Furthermore, its chemical composition by EDS don't indicatepathogenic elements presence on HMA matrix; considering the WFS residual origin. Inaddition, HMA microstructural analysis by SEM indicated a matrix uniformity composed ofspherical grains, predominantly. Being correlated to its satisfactory resistance to traction (RT), fatigue and resilience (MR) determined by typical road engineering tests.

EVALUATION OF POLYPROPYLENE COMPOSITES WITH POST-CONSUMER GUARANA FIBERS

The growing concern about environmental impact and the need for sustainable solutions have driven research seeking innovative alternatives for the reuse of waste, such as the residue from the guarana aroma extraction industry. Brazil, one of the world''s largest producers of guarana, generates a significant amount of this waste, making its reuse an opportunity to contribute to sustainability and minimize environmental impact. In this scenario, the search for solutions that integrate this waste into the production of composites, such as the incorporation of natural fibers into a polymer matrix, has gained relevance. This approach aims to combine ecological responsibility with economic efficiency, promoting sustainable development and reducing dependence on non-biodegradable and polluting materials. In this context, the study focused on the production of polypropylene matrix composites using residue from the guarana aroma extraction industry. Guarana fibers were used in two forms: as received and after an alkaline mercerization treatment, which aims to improve the interaction between the fibers and the polymer matrix. The aim of the work was to morphologically analyze the fibers before and after the chemical treatment and to evaluate the mechanical properties of the produced composites. To validate the results, a 2^2 factorial statistical analysis was performed, varyingthe percentage of guarana residue in the composites and the categorical analysis, using thefibers before and after treatment. The response evaluated was the properties of tensile, flexural, and impact strength. The composites were also compared with pure polypropylene. Preliminary results indicate potential in the use of post-consumer guarana fibers in the production of polypropylene matrix composites. If expectations are confirmed, this approachcan offer a sustainable and economic solution for waste management and the production ofrecycled materials.

Exploring Polypyrrole as Extraction Phase for Disposable Pipette Extraction (DPX) Method for Multiclass Organic Micro-Pollutant Determination in River and Tap Water Using Gas Chromatography-MassSpectrometry (GC-MS)

Ricardo Dagnoni Huelsmann[1], Francielle Crocetta Turazzi[1], Guilherme Mariz de Oliveira Barra[1], Eduardo Carasek[1]

[1]Universidade Federal de Santa Catarina

e-mail: dagnoni1995@gmail.com

Concern about the presence of organic micro-pollutants in natural waters is increasing, given the negative impacts on the health of various organisms, including humans [1]. Some classes of these contaminants are pesticides and endocrine disruptor compounds, as personal care products and plasticizers. They are frequently detected in environmental matrices, there is a need for the development of accurate, fast and safe analytical methods for the monitoring of these contaminants in aqueous samples. Thus, sample preparation (which aims to suit the sample to the instrument, preferably pre-concentrating the analytes) is a necessary and very important strategy. Among the sample preparation technique, a microextraction technique have gained a lot of visibility is disposable pipette extraction (DPX) [2]. One of the most positive features of DPX is the possibility of using differentextractive phases. Some of these materials are biosorbents or synthetic materials, like polypyrrole (PPy). The possibility of several interactions between PPy and analytes makesPPy an excellent alternative to be a extractor phase in DPX, is also highly stable, has highsurface area and, especially, is easy to synthesis [3]. This work aims to develop, optimizeand validate a fast and effective method for the determination of 18 organic micro- pollutants of five different classes in environmental waters by DPX using PPy as extractionphase, and GC-MS for separation and detection.

Oil production in Brazil has been growing year after year. One of the main oils produced in the country is palm oil, popularly known as dendê oil With this increase in palm oil production, there is also an increase in waste generation, particularly the bunches, which are discarded after removing the kernels [1]. In the search for applying these bunches, this research aims to find ways to give new employment for this material. Thus, chemical and physical tests were carried out on the fiber in natura and the extracted cellulose. They also were characterized by X-ray fluorescence (XRF), X-ray diffraction (XRD), and thermogravimetry (TGA) [2]. The results of the chemical analysis showed that the fiber from the palm oil residue presents significant percentages of cellulose (67.2%), being viable for application in composites since this polymer is directly correlated to mechanical properties. The FRX analysis showed potassium (K) as the main element present in the fiber, demonstrating this residue's value for applications in other areas. In the XRD analysis, the characteristic planes of lignocellulosic materials were observed; in addition, crystallinity was increased after its cellulose extraction (32 % to 49%). By TGA, it was possible to observe the thermal stability of the extracted fiber (Tonset= 355 ℃) and the cellulose (Tonset= 370 ℃), showing the possibility of being extruded and injected in a future composite production process. These results show that oil palm bunches can be applied topolymeric composites.

e-mail: islaineeli@gmail.com

The identification and revelation of latent fingerprints (LFP) are standard procedures in criminal investigatio however, currently, the information obtained by this technique can be amplified due to the analysis of markers in the fingerprints, such as biological material [1,2]. In this work, red emitting CdTe quantum dots (QDs) were incorporated under optimum conditions in Melamine-Urea-Formaldehyde (MUF) and Melamine-Thiourea-Formaldehyde (MTF) resins, which were applied as fluorescent powders for simultaneous marking and revelation of spermatozoa in latent fingerprints. The QDs displayed maximum fluorescence in the red region (λ_{ex}= 350 nm / λ_{em}= 590 nm), which was preserved after incorporation in the resin. However, for the MTF/QDs nanocomposite, a higher brightness and fluorescence intensity was found under UV light, possibly associated with the interactions with sulfur groups with Cd atoms of CdTe. LFP was applied in samples without and with semen contamination. The fingerprints revealed details such as pattern type and singular points, indicating high similarity with the donator's fingerprint exploring reference method. Besides, fingerprints with semen contamination were analyzed by optical microscopy, and spermatozoa were found with image resolution with fluorescence emission under UV light. Finally, fluorescent nanocomposites were applied to latent fingermarks deposited on various surfaces (paper, glass, wood, among others) and the marking of spermatozoa; thus, these results suggest that fluorescent powders developed can be used efficiently to help the resolution of sexual crime scenes.

Geopolymers are inorganic polymers, which are obtained through the polymerization of natural raw materials, of geological origin or by-product materials, containing aluminosilicates [1]. In the production of geopolymers, aluminosilicates are partially dissolved in alkaline solutions containing NaOH or KOH [1]. In geopolymer concrete, geopolymer is used as binder instead of Portland cement. The use of alternative sources of precursor materials is a possible solution for kaolin mining in Pará, which in its mining rocess discards materials rich in aluminosilicates that have no application in the paper industry due to contaminants and characteristics of the ore. The present work carried outchemical, mineralogical and microscopic characterization tests, in order to characterize theore called Hard Kaolin , which is not used as a source of kaolinite for the paper industry dueto technical difficulties in processing, but can be used as a source of aluminosilicates for theproduction of geopolymer concrete. A geopolymeric cement paste was produced and compared with other pastes produced from pure kaolinite and Portland cement, verifying itsmechanical properties through the simple compressive strength test. The results proved that hard kaolin can be an adequate precursor source for this application, and can be an alternative for this environmental liability generated in the kaolin mining activities of the sedimentary deposits of the state of Pará. This generated product also has an ecological,given the origin of its raw materials, minimizing the environmental impacts of miningactivities and taking advantage of a waste that has not yet been used.

The Wood is a raw material widely used in Brazil, and its abundant use in the country can raise concerns about the exploitation of native forests and the generation of waste in the environment. With the constant use of reforestation woods in the production of particleboards, and to reduce the use of resins usual in large panels, and to reduce the use of usual resins in large panel industries, one of the alternatives is desirable in this work, where it partially replaces wood in the addition of Polyethylene Terephthalate (PET). In this study, the present work has to production and evaluation of homogeneous agglomerated panels with shaving from Pinus elliottii, Pinus taeda and PET, bonded with polyurethane derived from castor oil (PUR), with the objective of influence of the addition of PET. Tree blends were presented (two blends containing wood, PET and PUR, and a reference blend with no PET added). For each mixture, tree panels with a nominal density of 0,35 g/cm³ were produced, pressed at a temperature of 160ºC for 6 minutes and a pressure of 70tf. Thepanels were evaluated for their physical end mechanical properties based on the ABNT NBR[1,2] and ASTM [3]. According to the results obtained, the modulus of resistance to staticflexon (MOR) and modulus of elasticity (MOE) were determined, therefore, they were classified as ABNT NBR and ASTM.

Incorporation of transition metal salt in obtaininghybrid organic-inorganic silicon polymers by hydrosilylation reaction

Alexandre Costa Guimarães Cruz[1], Paulo Rodrigo Stival Bittencourt[2], Mariana Gava Segatelli[1]

[1]Universidade Estadual de Londrina (*Química*) , [2]Universidade Tecnológica Federal doParaná (*Química*)

e-mail: alexandrecosta.guimaraescruz@gmail.com

The purpose of this study was to prepare hybrid organic-inorganic silicon oxycarbide (SiOC) precursors with different amounts of nickel chloride to evaluate their physical and chemical changes. Polymers were synthed by hydrosilylation reaction between 60 wt.% poly(methylhydrosiloxane) (PHMS) and 40 wt.% divinylbenzene (DVB) containing 20 wt.% polyethylene (PET) and different percentages in mass of $NiCl_2$(0,1,3,5,10 and 20 wt.%), previously dried in the oven. Diffuse reflectance experiments showed that the greater amount of NiCl2 increased the percentage of maximum reflection at 590 nm. TG curves ofNi -free and -containing polymers were like each other, indicating that the presence of NiCl2 did not influence the thermal degradation. The DTG curves showed degradation eventsin 155 ℃ related to H_2O loss for the $NiCl_2$, at 460.6 ℃ (Tmax) characteristic to degradation of matrix PHMS and DVB and at 520 ℃ referent to degradation of PET. FT-IR spectra of thepolymeric matrices indicated that the reaction between DVB and PHMS occurred, due to thedecrease of relative intensities of νSi-H and νC=C absorptions and arising of νSi- $CH_2CH_2$when compared to pure reagents. The polymer crosslinking degree was investigatedby the ratio between νSi-H and νSi-CH_3bands and study of swelling effect test in 10 mL hexane for 24 hours stirring for 0.1 g of each polymers. Both results revealed that the presence of salt favored crosslinking even for 5% wt.% $NiCl_2$material and the materials with10 to 20% the crosslinking was similar to the system without Ni salt. SEM microscopy willbe performed to verify dispersion of $NiCl_2$in polymers. The homogeneous distribution of Ni isdesired since the transition metal associated with a static atmosphere of argon catalyzes theformation of graphite properly dispersed structures implying an application of SiOC material for systems where electrical properties are required.

e-mail: mauricio.baesso@gmail.com

Energy efficiency has always been one of the main objectives when designing mechanical systems. Fiber-reinforced polymers provide great chemical stability and higher strength-to-weight ratio when compared to traditional metals, hence their wide acceptance in automotive components [1,2]. However, possessing the desirable material is not enough without the appropriate processing method. Injection molding is categorized as an additive manufacturing process which enables the production of complex parts in a short period of time. Therefore, the present study - through the design of experiments (DOE) via Taguchi Method - aims to evaluate the influence of this process on mechanical properties and morphology of such material more specifically on glass-fiber reinforced polyamide with a fiber content of 35 %. The analyzed parameters were injection pressure, temperature, and injection speed. Specimens' density and volume of voids were obtained by Archimedes' Principle; SEM³ allowed the analysis of fiber orientation, and possible voids. DSC³ and tensile testing provided the effect of parameters on the material's crystallinity and mechanical properties such as ultimate tensile strength, Young's modulus and elongation before break. Lastly, using Taguchi Method, such parameters were ranked in order of influence on the aforementioned properties.

Industries that seek to develop new products, the faster and more agile this development is, the greater the chance for the industry to place this product on the market. Polymers play a key role in this industrial context, being used in several áreas and the injection molding being one of the most important industrial production processes. However, the negative factor associated with this process is the time and high cost required for tooling development. Additive manufacturing (AM) is currently a prominent production process, with the ability to create parts from a three-dimensional model. In this context, the development of injection mold cavities using AM processes becomes an excellent alternative to assist and speed up the development of tooling required for thermoplastic injection processes. Studies demonstrate that this topic is of great relevance and is already used in some sectors. However, the AM of injection molds using SLS (selective laser sintering) technology is little explored in the scientific and industrial fields. In this work, a hybrid mold was developed using injection cavities produced through AM by SLS technology and machining. The mechanical limits for cavities produced by AM and the durability of cavities produced in Polyamide 12 (PA 12) were evaluated, using polypropylene (PP) test specimens as a reference for injection. The mold was designed to perform the injection of 4 cavities simultaneously, with 2 variations of materials produced by SLS and 2 machined in a metallic material, ensuring that the process parameters are similar for all materials. The test specimens were mechanically characterized by testing tensile strength and flexural strength, as well as dimensional analysis, and the surface of the test specimens was analyzed by scanning electron microscopy (SEM) and thermal analysis. The mold was effective for a pilot model, as it was possible to perform 105 injection cycles, a value that is superior when compared to other authors.

Investigating the Mechanical and Thermal Propertiesof PVC Incorporating Reduced Graphene Oxide Synthesized via Modified Hummers' Method.

Luca Bisognini Cuba[1], Lucas Sobral Apolaro e Silva[2], Natalia Oliveira Morgueto[1], Fabiano Caio Jose[1], Thiago de Carvalho Cipriano[1], Gustavo Spina[3], Luiz Henrique Vasconcelos[4], Kerley Cristiane Victorino Romao[5]

[1]Escola e faculdade SENAI "Mario Amato", [2]Centro Universitário Fundação Santo André (*Engenharia*) , [3]Instituto SENAI de Inovação - ISI, [4]Escola e Faculdade SENAI Mario Amato, [5]Escola e faculdade SENAI Mario Amato

e-mail: luca.cuba@senai.edu.br

The aim of this study was to synthesize reduced graphene oxide (rGO) from graphite via the modified Hummers' method, and to investigate the incorporation of rGO into flexible Polyvinyl Chloride (PVC) and its resulting properties. Raman spectroscopy and scanning electron microscopy (SEM) were used to analyze the structural, chemical, and morphological properties of the synthesized rGO, which was subsequently incorporated into flexible PVC for polymer characterization tests of mechanical and thermal properties. Graphite was first converted into graphene oxide (GO) using the modified Hummers' method, followed by its reduction to rGO, and incorporation into flexible PVC. The structural, chemical, and morphological properties of both graphite and rGO samples were characterized using Raman spectroscopy and SEM. Polymer characterization tests were conducted to assess the mechanical and thermal properties of PVC with and without rGO. It is expected that the incorporation of rGO will enhance the mechanical and thermal properties of PVC. In particular, the thermal stability of PVC is expected to improve with the addition of rGO, as indicated by the results of thermogravimetric analysis (TGA). Specifically, the thermal decomposition temperature is expected to increase from 180°C to 200°C to 210°C to 215°C. Overall, the incorporation of rGO synthesized from graphite intoPVC has promising potential to contribute to the understanding of the synthesis of rGO viathe modified Hummers' method, and its application in polymer science.

In vitro antimicrobial activity of photo-irradiated safranin-based film-forming solutions as antiseptic in bovine mastitis

Marcela Saager Dias[1], Gabriela Iantorno de Souza[2], Rita Cristina Gonçalves de Melo[1], Lilian Gasparelli Carreira[1], Juliana Alves Resende[1], Marco Túlio Costa Almeida[1], Janaina Cecília Oliveira Villanova[3]

e-mail: marcela.s.dias@edu.ufes.br

The search for alternative therapies to treat bovine mastitis has been a highly studied topic due to the emergence of multiresistant bacteria [1]. Safranin-O (SFO) is a photosensitizer agent that, when activated by visible light is capable of damaging structures and causing microorganisms death, including Gram-positive bacteria which causes mastitis [2]. This study aimed to prepare in situ film-forming polymeric solutions (FFPS) containing SFO fortopical administration onto cows' teats followed by photoirradiation, to act as antiseptic. The effectiveness of FFPS in inhibiting the proliferation of standard strains of *Staphylococcus aureus*was evaluated. The FFPS were prepared using pure poly(vinyl alcohol) (PVA; Mw = 13.000 to 23.000 Da; hydrolyzed grade = 87 to 89%) at 18% w/w or PVA blended with poly(acrylic acid sodium salt) (PAAS; Mw = 2.100 Da) at 20% w/w. The SFO was incorporated at a concentration of 0.84% w/w. The antimicrobial activity was evaluated by *in vitro*method, with and without exposure to a green LED light (520 nm) for either 1 or 5 min. Both the pure SFO solution (0.84% w/w) and the PVA film were unable to inhibit bacterial proliferation, with and without photoirradiation and, at both times. It was also observed that the photo-irradiated FFPS based on PVA and SFO were able to inhibit the strains of*S. aureus*from proliferation, proving their efficacy. The photo-irradiated FFPS based on the PVA and PASS blend, with and without the presence of SFO, were also able to inhibit bacterial proliferation, suggesting that the photo-irradiated PAAS has antimicrobial properties. The FFPS containing SFO showed promising results for antiseptic use and the antimicrobial activity of photo-irradiated FFPS based on PAAS will be further studied.

e-mail: darenas@gmail.com

The textile industry''s significant advances have caused serious environmental problems since they generate a considerable amount of effluent contaminated with dyes, becoming a concern for governments and environmental protection agencies. This study aimed to obtain an aptmized reusable adsorbent composite (CP) based on polyaniline (PANI) conductive polymer with magnetite (PANI/Fe3O4) for the removal of methylene blue (MB) dye in aqueous solution. The materials were characterized and optimized concerning pH, temperature, and adsorbent concentration. Additionally, an adsorption study was carried out to understand the chemical processes involved, and the reuse of the adsorbent materialwas tested. The results showed that the composites present favorable physicochemical properties for dye adsorption, and the CP 50:1 presented the best performance. Kinetics and equilibrium studies showed that the adsorption process can be described by the pseudo-second-order kinetic and Langmuir isotherm models, respectively. The proposed methodology proved to be efficient for obtaining low-cost adsorbents with the possibility of recovery and reuse in the MB dye adsorption process.

e-mail: maciel.homero@gmail.com

Extreme aerothermodynamic environmental condition arises in hypersonic flight, reentry space vehicles, and modern gas turbines. Inconel superalloys have good oxidation and erosion resistance but has limited operational temperature (850 oC) [1]. Composite C/C, commonly used in aircraft structures due to its low weight and cost, degrade rapidly in a high catalytic oxidizing environment, resulting in loss of its mechanical and structural properties [2]. The solution for such a defying ambient is to place a protective barrier, known as environmental barrier coating (EBC), these coatings are used when the ambient is extremely reactive, with high temperatures and ablatives environment. Next generation EBCs will require stable oxide phases formation, high density, homogeneity, thermal shock resistance, fracture resistance and high thermal conductivity. A worthy candidate, mullite (3Al2O3.2SiO2), is suitable to form composite material and has high chemical stability. In these context thick Environmental Barrier Coatings (EBC) were deposited in carbon-carbon composite using hybrid precursors of alumina and zircon through the high-velocity plasma spray technique [3]. The hybrid precursor consists of a solid dispersed in a solution, both contributing to the coating formation. The EBC's were evaluated in microstructure and composition by the following characterization methods was used, namely DRX, FTIR, Raman spectroscopy, and MEV.

Multifunctional materials (MFMs) can be an important system because of their capacity to combine different properties useful for electronic devices [1]. Multiwalled carbon nanotubes (MWCNTs) and azobenzene derivate Sudan III (SIII) are compounds with great potential to form this type of system. These compounds exhibit properties of electrical conduction and photoinduced molecular orientation, respectively, which can be combined in a single film-shaped system. In this study, we report on the fabrication and characterization of multifunctional hybrid films created from SIII mixed with MWCNTs via both Langmuir and Langmuir-Blodgett (LB) techniques. For SIII+MWCNTs monolayers obtained using the Langmuir technique, the surface pressure isotherms revealed that the aggregation process of pure SIII drives the formation of monolayers. Brewster angle microscopy of the monolayers indicated that MWCNTs form loop-shaped structures resembling rings. Such structures were not present in films of pure MWCNTs or pure SIII. The current-voltage characteristic curve showed that the films have an ohmic behavior associated to free electrons in MWCNTs, exhibiting conductivity on the order of that of semiconductors. The SIII+MWCNTs LB films exhibited a photoinduced molecular orientation determined via SIII photoisomerization. These processes, occurring in a single film, are the conceptual proof that these systems are MFMs with potential applications in developing hybrid devices.

e-mail: stefeson@msn.com

The study aimed to investigate the relationship between the production of P(3HB) (a biopolymer with diverse applications) and four independent variables: glycerol, inverted sugar, temperature, and the concentration of Xt in the culture medium. P(3HB) is a valuable biopolymer known for its potential in medical, environmental, and packaging industries. Multiple regression analysis was conducted using data obtained from a published article [1] to analyze the impact of these variables on P(3HB) production.

The results revealed a strong positive correlation ($R=0.896$) between the dependent and independent variables. The included independent variables accounted for 80.3% of the variability in P(3HB) production, as indicated by the coefficient of determination ($R^2=0.803$). The model was statistically significant ($F=12.231$) with a significance level of 95% ($p<0.00034$), indicating that the regression model adequately captured the relationship between the variables.

Further analysis demonstrated that only the concentration of Xt in the culture medium had a significant effect on P(3HB) production, with a p-value less than 0.05. This finding suggests that increasing the concentration of Xt in the culture medium leads to a corresponding increase in P(3HB) production. However, there was insufficient evidence to suggest significant effects of glycerol, inverted sugar, and temperature on P(3HB) production.

In summary, this study emphas the significance of Xt concentration in the culture medium for maximizing P(3HB) production. By understanding the relationships between the independent variables and the dependent variable, researchers and industries can optimize the production process and harness the potential of P(3HB) in various applications.

e-mail: arthurltfb@gmail.com

The Uncaria tomentosa has been widely used in traditional medicine, decoctions made from its bark are used for the treatment of various diseases, being the anti-inflammatory activity described as the main pharmacological application, however despite the great benefit its use in the nutraceutical industry is still restricted due to low stability [1]. Thus, for its use is important the application of techniques with protective effect. In this sense, the present work aimed to develop starch microcapsules by spray drying containing macerated ethanolic extract of U. tomentosa bark powder. The ethanolic extract and microcapsule were submitted to chemical and physicochemical characterization and antibacterial activity assays. The results of the characterization of the extract and microcapsules reveal the presence of alkaloids (Dragndorff test) and phenolic compounds (UPLC-DAD). The formation of microcapsule composition was observed by SEM and FTIR. Dissolution tests demonstrated that microcapsules have the characteristic of being poorly soluble in water and the addition of pharmacotechnical adjuvants can aid in the better release and absorption of the active components, reaching ~80% release. The extract and microcapsules presented antioxidant activity with IC50 values of 5.80 and 5.03 μg/mL. The partitioned extracts showed activity against strains of gram-negative and gram-positive bacteria, fraction UT-7 performed best on all strains, reaching MICs below 256 μg/mL, probably dueto the synergistic effect of alkaloids and phenolic compounds. Given the above, the assays performed in this work show the importance of monitoring the quality of Uncaria tomentosa encapsulates to avoid losses by volatilization or decomposition during processing steps and the need for special storage conditions of the extract in solid form.

O uso de matérias-primas de fontes renováveis vem constituindo um objeto de estudos e pesquisas de diversas instituições, devido ao seu potencial na substituição de produtos derivados do petróleo. Com base nessa afirmação, o objetivo deste estudo foi obter e caracterizar filmes biodegradáveis constituídos por blendas ternárias de biopolímeros. Os filmes produzidos foram compostos por quitosana, fécula de batata e alginato de sódio, combase em um planejamento experimental empregando plano ternário de mistura. As soluçõesfilmogênicas foram obtidas pela técnica casting, com a matéria seca fixa em 2%. O plastificante utilizado foi o glicerol e sua porcentagem foi fixa em 20%, em relação à massaseca de biopolímero. Após a produção dos biofilmes, estes foram cortados em corpos deprova, para a realização da caracterização físico-química, MEV, solubilidade, PVA, cor eopacidade. Foi realizada uma análise de variância para obtenção dos modelos e o Teste Fpara verificar a significância estatística destes. Após essa verificação, foram gerados os gráficos de superfícies de respostas. A partir das superfícies e dos modelos obtidos foi possível avaliar o efeito da composição das blendas biopoliméricas sobre os parâmetros desolubilidade e permeabilidade ao vapor de água. As morfologias das superfícies dos filmesforam analisadas através das micrografias obtidas (MEV). A concentraçãode quitosana naformulação dos filmes influenciou negativamente a propriedade de solubilidade, visto que aquitasana é cerca de 15% menos solúvel e isso ocorre devido a presença de grupamentosamino livres, sendo dessa forma insolúvel em água. Os filmes que continham a presença dafécula de batata obtiveram melhores propriedades de barreira, em relação a blenda que apresentou a menor taxa de permeabilidade ao vapor de água, apresentando ser cerca de15% menos permeável. A partir da morfologia de superfície analisada foi vista a formação compacta e homogênea.

Optimization of self-compacting soil-cement for the manufacture of bricks with the incorporation marble powder and construction waste.

e-mail: gean.jr@unesp.br

The objective of this study was to evaluate the influence of marble powder and construction waste on the behavior of self-compacting cementitious soil (SCCS) for brick manufacturing. The parameters of soil, cement, water, and additive were adopted based on recent studies on SCCS. An optimization study was carried out to determine the appropriate proportions of marble powder and waste for brick production. In the fresh state, spread tests in the free regime and confined flow tests from the funnel were performed, while in the hardened state, cylindrical specimens were produced and subjected to axial compressive strength tests at 7, 14, and 28 days and absorption tests. In addition, bricks were produced and tested for compressive strength and absorption. The results showed that the proportion of marble powder and construction waste contributed to better workability conditions and control over flow and segregation in the fresh state. In the hardened state, the best mechanical performances were achieved with 20% marble powder and 10% construction waste, which were adopted for the bricks. The produced bricks presented mechanical strength results around 6.4 MPa and 19.7% absorption. The results indicated that the use of marble powder and construction waste is a viable alternative for manufacturing bricks with satisfactory mechanical and absorption properties.

In view of the different possibilities of using synthetic polymers, they have been mass-produced since the 1940s and, since then, they have been used in the manufacture of several industrial products for everyday use. However, the intensive use of non-biodegradable polymers has caused environmental problems all over the world, such as the contamination of terrestrial and marine ecosystems. [1,2]. Gradually, the plastic waste disposal strategy by industries has been changing. Instead of incinerating plastic waste, which releases toxic products into the environment, government policies have been encouraging the use of biodegradable polymers and creating policies to encourage recycling and composting [3]. The aim of this work was the fabrication of an impermeable and biodegradable starch-based bionanocomposite film filled with graphene oxide to increase moisture resistance, mechanical and thermal stability. Chemical characterization was performed by Fourier transform infrared and Raman spectroscopies, thermal stability and moisture resistance was evaluated by thermogravimetry and contact angle measurements, respectively. Morphology was observed by scanning electron microscopy images. The results obtained in this work showed a reduction in the water absorption of the starch films when 0.1 wt.% of graphene oxide was incorporated in the formulation turning this film a good candidate for application as an intermediate layer in packages based on multilayer films, reducing the use of synthetic plastics or metals and, consequently, minimizing environmental impacts.

e-mail: dark.snake.br@gmail.com

Electrical conductivity and structural durability are essential for their versatile applications of polymer nanocomposites such as electromagnetic radiation absorption, conductive adhesives, and sensors. The incorporation of conductive nanostructures such as graphene isa promising method for conferring conductivity to polymers. Graphene''s high aspect ratio, conductivity, specific surface area, and mechanical strength have made it an excellent choice for the preparation of conductive polymer composites. Understanding the relationship between structure/morphology, processing and final properties is essential for the design and production of materials with appropriate properties for the various emerging applications. In this context, this work investigates the morphology and the transport of electric charges between poly (ethylene terephthalate) (PET) and two types of commercial graphenes incorporated through the melt mixing technique. The results indicate that produced nanocomposites exhibit some type of variation in electrical conductivity, however, there was no significant improvement in the electrical conductivity of the PET/graphene nanocomposites with concentrations ranging from 0.001 to 1 phr. While the other PET samples with exfoliated graphene of smaller lateral size indicated an increase of 44 % in Young''s modulus in relation to pure PET. A relevant result of this study is that for the optimal concentration of 0.1 phr, the use of the smallest lateral size graphene promotes an improvement in mechanical properties in relation to the Young''s modulus.

[1]Instituto Federal de Educação, Ciencia E Tecnologia de Brasilia, [2]Universidade de Brasília (*Instituto de Química*) , [3]Instituto Nacional de Criminalística da Polícia Federal

e-mail: aline.arouca@ifb.edu.br

Proximity Firefighting Protective (PFP) Clothing is part of firefighters' personal protective equipment and are developed from fiber blends of aromatic polyamides (Nomex®, Kevlar®and carbon). The integrity of this material is extremely important because it allows firefighters′ thermal and physical protection. On the other hand, PFPs are impregnated with toxic compounds such as PAH and can serve as a source of contamination for firefighters - so they need to be periodically decontaminated properly. One of the ways of decontamination can be through photolysis. Fibers exposure to radiation is a concern, as it can triggers radical reactions promoting material degradation by photolysis reactions[1]. Considering that, we promoted a 3-day and 30-day photolysis PFPC fabric (Unishell®, 58% kevlar®, 40% nomex®, 2% carbon and Teflon® coating) using a light radiation (λ = 283,322, 353, 465, 496, 498, 545 and 577 nm). The fibers′ damage was verified by attenuatedtotal reflection Fourier transform infrared spectroscopy (FTIR/RTA) and scanning electron microscopy with energy-dispersive X-ray spectroscopy (SEM/EDS). Also, a tear resistance test was performed after a 30-day experiment. The FTIR/RTA showed no formation forming acids, alcohols and/or amines, know photolysis by-products[2]. In SEM images no differences were observed fibers morphology. The tear resistance test presented a reduction of 17%-26% after 30-days photolysis. This reduction is not necessarily due to fiber degradation but can be related to removal of Teflon®, evidenced by decrease of fluorine inEDS maps. In view of these results, even after the 30-days photolysis, the integrity of aromatic polyamides fibers maintained.

e-mail: luiztakegami@estudante.ufscar.br

Hydrogels are three-dimensional materials that show the ability to absorb large quantities of water without dissolving. These materials can also respond to stimuli such as pH, temperature, biological molecules, and other properties, and can act in the release of drugs depending on internal and external stimuli, and thus can be classified as intelligent biomedical materials.

Among the polymeric hydrogels, those based on chitosan present interesting characteristics for biomedical applications, such as biocompatibility, gel-forming ability, non-toxicity, and biodegradability. However, some polymeric hydrogels can show poor mechanical properties when compared to other materials, which would limit their applications in specific areas. The incorporation of inorganic nanoparticles into the biopolymer-hydrogels matrix can increase the mechanical and biological properties of the final nanocomposites.

A series of chitosan hydrogels and TiO_2-OPM nanoparticles prepared via an aqueous formulation, only in the presence of ammonia vapor, which induces the gelation process. To compare the effect of peroxo groups on the surface of nanomaterials, TiO_2-OPM nanoparticles were heated at 250°C for 30 min under H_2, generating materials with reduced surfaces free of peroxo groups.

Different factors that affect the properties of hydrogels were investigated through structural, thermal, spectroscopic, and optical characterization. In order to use the material as a vehicle for the controlled release of drugs, the final hydrogels were submitted to loading and release tests with dyes. Results showed that nanomaterials improved the structural properties of hydrogels and showed potential use for drug delivery.

e-mail: estercosta@ufrrj.br

An oil spill on roads can be a hazardous situation that needs to be dealt with promptly to avoid accidents and prevent environmental damage. The use of absorbent materials like sand, sawdust, or kitty litter to soak up the oil has been considered. These materials will absorb the oil and make it easier to clean up. It is essential to take immediate action when an oil spill occurs on roads to minimize the damage and prevent accidents. In the present work, films of bulgur [1] and poly(lactic acid) (PLA) (PLA/Bul) were produced to achieve an amphiphilic material. Bulgur (also spelled burghul) is a grain made from whole wheat, and PLA is a biodegradable and compostable polymer [2] that is produced from renewable resources such as cornstarch, sugarcane, or cassava. While bulgur and PLA are organic materials, they are different in their composition and properties, allowing the production of amphiphilic materials. PLA/Bul (with the following composition (PLA: Bul) 90:10; 70:30; 50:50) were produced by compression molding technique and characterized by Scanning electron microscopy (SEM) and FTIR. The film's water and oil absorption (soy oil) were investigated. Composition strongly affected morphology and the amount of water and oil absorbed, as stated by SEM. FTIR indicates that no chemical changes occurred in bulgur and PLA. For 15 minutes, the water absorption of the PLA: Bul films was higher in the samples with the highest amount of bulgur, reaching absorption of approximately 28% wt. However, oil absorption was more expressive in the 70:30 film reaching around 10% wt. These results demonstrate the amphiphilic character of the film associated with the composition.

e-mail: mconceicao@cetem.gov.br

Preparation of bionanocomposites, using low percentages of inorganic fillers, is one of the routes to improve some of the properties of biodegradable polymers such as polyhydroxybutirate (PHB). This is because it is environmentally friendly and available in large quantities at relatively low cost [1]. As clays are naturally hydrophilic, in order to make the hydrophilic silicates more compatible with polymers, the cations between the layers can be changed by cationic surfactants like the alkyl ammonium [1,2]. The modified clay becomes organophilic (Bento) and its surface energy decreases and the interbasal distance increases. When the hydrophilic clay (Bent) is rendered hydrophobic (Bento), the interfacial adhesion among the polymer/clay nanocompos-ites phases is enhanced. Furthermore, it makes possible the polymer molecules intercalate inside clays galleries [1,2]. In this work, PHB biocomposites were processed by extrusion in the following PHB/Bentonite wt.%: PHB (100/0); PHB/Bent (90/10); and PHB/Bento (90/10). The samples were characterized by FTIR, SEM, X-ray diffraction, Density, Hardness and Contact angle measurement. New bands corresponding to the alkyl ammonium salt showed intercalation of the quaternary cation in the interlamellar spaces of Bento, according to FTIR/ATR results. DRX diffractogram of Bent indicated the presence of impurities such as quartz, kaolinite and illite; Bento's diffractogram indicated an expansion of the basal layers of the material and that its structure was less crystalline. The density results for formulations PHB, PHB/Bent and PHB/Bento were 1.259 ± 0.03, 1.122 ± 0.04, and 1.337 ± 0.02, confirming a good adhesion with PHB matrix, when organophilic bentonite was used, which corroborate the SEM micrographs.

Vitrimers have emerged as a class of polymeric materials with good chemical and mechanical resistance that, in turn, can be reused and recycled. These properties turn vitrimers into an interesting alternative to other polymers in developing a circular economy. Recently, self-healing capacity and recyclability have arisen as some of their desirable characteristics. In this context, the synthesis of polymeric micro or nanocapsules mixed with the vitrimer has emerged. These capsules contain a dye system that is released and activated chemically or physically when the capsule is damaged, showing the place and moment a vitrimer is damaged [1].

The synthesis of polymeric polymethylmethacrylate (PMMA) nanocapsules containing crystal violet lactone (CVL) as a change indicator substance (dye) was studied, employing the emulsification technique. The amounts of PMMA and surfactant, pH and ultrasonic amplitude were varied to evaluate their influence on the and thickness of the capsules. The hydrodynamic was determined by DLS, and the morphology and formation of the capsule were also studied by TEM and SEM. According to our results, 1% is the optimal amount of surfactant, and ultrasonic amplitude plays no critical role in nanoparticle . In addition, the of the nanoparticles increased with the amount of PMMA.

In this work it was developed an experimental design to achieve an optimized preparation process of PMMA/CVL nanocapsules giving rise to a pathway to study their incorporation into a vitrimer model and the demonstration of their functionality. Achieved this, we will be able to advance in the development of the self-repairing capacities of the material and thus contribute to an improvement in the circularity of the economy.

e-mail: william.ottoni@ufpe.br

This work presents the characterization by torque rheometry, DSC and SEM of PET/PA6 blend composites with sugarcane bagasse ash, synthetized in a Mixer at different mass compositions with some of the compositions having the addition of Joncryl (Jc), a chain extender. The additivated composites presented higher values of stable torque than the ones of the same composition without the extender, however, only the compositions 50%PET/50% PA6 Jc and 100% PA6 presented a positive degradation rate, which means that the chain extension occurred in a way it compensated the degradation during the processing. It was observed through the DSC curve that the polymers, specially the PET, in many of the compositions, presented a higher degree of crystallinity when compared to the neat polymers, indicating that the ash increased the crystallinity, while the additivated composites overall had a decrease in their crystallinity degree, another indication of chain extension. In some of the compositions (75% and 25% PET), the cold crystallization of PET did not occur, which improves its processing and molding, specially through injection stretch blow. All the composites presented a noticeable increase regarding the maximum crystallization rate when compared to the neat polymers, indicating that the sugarcane bagasse ash might have acted as a nucleating agent. At last, although the DSC curve suggested that the blend was immiscible because of the presence of two melting and crystallization peaks, the SEM of the composites showed that the addition of Joncryl appears to have increased the compatibility between polymers.

Preparation of core Shell particles for controlledoxygen release

Mariana Chaves Santos[1], Gustavo Fernandes de Sousa[1], MOISES DAS VIRGENS SANTANA[1], Anderson Oliveira Lobo[1]

e-mail: marianachaves.santos@gmail.com

Microspheres synthed via the core shell have been used in applications in cells under hypoxic conditions were also demonstrated. The double-layer system allows for the controlled release of oxygen at the optimal level for muscle cell survival. Various approaches have been employed to design and manufacture polymer particles, such as solvent evaporation, emulsion diffusion, nanoprecipitation, microfluidic device, and electrospray. PLA, PCL AND PCO form used microparticles and chloroform as solvent. They are analyzed through optical microscopy and oxygen release test. Resulting in the release of three days in a hypoxic environment and presented spherical morphology where it was possible to observe the formation of the nucleus and the shell. The promising results of this work are translatable to a future regenerative medical application.

Preparation of High Thermal Resistance Polyethylene Nanocomposites with Graphene Oxide for Applicationas Barrier Layer in Oil Pipelines

Barbara de Salles Macena da Cruz[1], Elen da Silva Santos[1], Lucas Galhardo Pimenta Tienne[1],
Maria de Fátima Vieira Marques[2], Erica Gervasoni Chaves[1]

e-mail: barbaracruz@ima.ufrj.br

High thermal resistance polyethylene (PE-RT) has a unique molecular and crystallinestructure, providing excellent long-term hydrostatic resistance at high temperatures (upto 90 ºC), competing with more expensive engineering polymers. In flexible pipelines,the internal pressure barrier layer must be leakproof. PE-RT is a special type of HDPE with raised temperaturecapability, designed with bimodal resin technology, containing long tie molecules in itscrystalline structure that play a key role in the long-term ductile creep behavior(GRABMANN et al., 2018). It is intended for applications in extreme conditions, suchas aggressive chemicals and hydrocarbons. Graphene oxide sheets (GO) arenanomaterial with numerous applications, mainly due to their high rigidity and gasbarrier properties. It could play an important role as a nanofiller to further improve PE-RT properties. The present work studies the development of PE-RT nanocompositescontaining 0.5, 1.0, and 2 wt.% GO (prepared by oxidation and exfoliation ofcommercial graphite), processed in a twin-screw extruder, and the properties wereevaluated. The results showed that, in all compositions, the addition of nanofillersincreased the thermal stability by up to 13 ºC at the initial degradation temperature ofthe composites, indicating the increase of barrier property. Hardness increased from 50to 59 shore (D) in the composites containing the highest nanofiller content. Thecrystallinity degree increased by 22% for nanocomposites with 0.5% GO comparedwith the pure matrix, and SEM images confirmed good filler dispersion of nanofiller inthe polymeric matrix. Production of a voltammetric sensor based on SiOC ceramic material for the simultaneous determination of caffeine, theophylline and peroxidine

Maria de Almeida Silva[1], Renata Santos Vieira da Conceição[2], César Ricardo Teixeira Tarley[2,3], Mariana Gava Segatelli

[1]Centro Universitário Leonardo da Vinci, [2]Universidade Estadual de Londrina, [3]Universidade Estadual de Campinas (*Química*)

e-mail: marialmeidas27@gmail.com

The objective of this work was the production of a voltammetric sensor based on carbon rich SiOC ceramic material for the simultaneous determination of caffeine, theophylline and pyroxidine. The ceramic material was obtained by controlled pyrolysis of a precursor polymer based on the radical reaction between polysiloxane poly(dimethylsiloxane-co-diphenylsiloxane) and Bisphenol A Glycerolate Dimethacrylate, at 1500 °C for 3 hours of annealing. To produce the voltammetric sensor, a paste electrode was produced in the proportions 80:20 (m/m) of ceramic material and nujol® mineral oil, respectively. The simultaneous determination of caffeine, theophylline and pyroxidine is currently little explored and are substances found in large amounts in energy drinks [1]. The ceramic material was characterized by XRD, N2 physiosorption at 77 K and Infrared, Raman and excited photoelectron spectroscopy, which confirmed a relevant amount of conductive (Csp2) and semiconductor (SiC) phases. The voltammetric sensor produced showed a separation of the voltammetric signals, referring to each analyte, more efficient than the commercial glassy carbon electrode and the method for the quantification of the molecules in question is in the finalization process. Furthermore, it is noteworthy that the application of SiOC ceramic materials as electrode materials to produce voltammetric sensors is still little explored, mainly in the simultaneous determination of analytes.

The numerous and structural diversity of pathological microorganisms, along with their mutation capabilities and possibility to cause infectious diseases, shows the need of solutions based on materials capable of inactivating microorganisms on direct contact, that will not be easily overcome by mutations that may be developed [1,2]. Quaternized polyethylenimine (QA-PEI) is promising against a broad spectrum of microorganisms because its quaternary nitrogen atoms can cleave their cell wall or lipoprotein envelope, releasing their genetic material to an extracellular environment [2,3]. In this work, blends of QA-PEI and polyvinyl alcohol (PVA) were produced by solution mixing and drop-casting, producing film samples with QA-PEI proportions of 0%, 1%, 2%, 5%, and 10% in weight into the PVA matrix. Inhibition halo tests performed against both gram-positive S. Aureus and gram-negative E. Coli showed that QA-PEI was effective in inhibiting these microorganisms even at the lowest QA-PEI concentration, as a clear inhibition halo was shown for the PVA/1% QA-PEI sample and their radii increased for both bacteria as QA-PEI concentration increased. TGA analyses showed that the thermal resistance of the samples decreased as QA-PEI concentration raised, although all of the samples only showed significant weight losses starting at temperatures above 300°C. Tensile tests showed a slight increase in the yield point values as the QA-PEI concentration increased, probably due to an electrostatic crosslinking effect between the positive quaternary nitrogen atoms of QA-PEI and the PVA hydroxyl groups. UV-Visible transmittance analyses showed no significant differences between pure PVA and the produced blends.

Production of cellulose acetate membranes modified with graphene oxide and inorganic oxide nanoparticles

Djanyna Voegel de Carvalho Schmidt[1], Jair Carlos Checon de Freitas[2], Cleocir Jose Dalmaschio[1]

[1]Universidade Federal do Espírito Santo (*Departamento de Química*) , [2]Universidade Federaldo Espírito Santo (*Departamento de Física*)

e-mail: djanyna.schmidt@edu.ufes.br

The increasing production of pollutants has negatively impacted the environment and human health [1]. To ensure environmental sustainability, it is essential to prevent the overuse of natural resources and properly dispose of waste [2]. In this context, the use of membranes to separate oil and water emulsions has been a promising technique, mainly to filter extensive effluents. This work studies the application of cellulose acetate membranes modified with graphene oxide and nanoparticles of inorganic oxides for use in the ultrafiltration of oil/water emulsions. The extraction of cellulose from vegetable sponge was followed by the organosolv method in order to obtain the cellulosic pulp [3]. The acetylation of the cellulose obtained was conducted by the homogeneous acetylation method [3]. The analysis of FTIR spectra indicated the disappearance of bands from lignin and hemicellulose. In addition, the spectrum of cellulose acetate showed the characteristic band of the acetyl group and the disappearance of the band corresponding to the cellulose hydroxyls, which indicates the synthesis of the material. The viscosimetric molar mass was determined and the degree of acetylation was obtained chemically, indicating the formationof cellulose triacetate. The produced membranes were then modified with the insertion of graphene oxide and inorganic oxide nanoparticles (e.g., TiO_2), aiming their use for the treatment of oil-in-water emulsions.

PRODUCTION OF RECYCLED BIODEGRADABLE COMPOUND FROM PAPER AND COCONUT FIBER FOR SEEDLINGS

ISAAC ANDERSON ALVES DE MOURA[1], Joelda Dantas[2], Elvia Leal[3], Kelly Cristiane Gomes[4,5]

[1]Universidade Federal da Paraíba (*PPGEM*) , [2]Universidade Federal da Paraíba (*Centro de Energias Alternativas e Renováveis*) , [3]Universidade Federal de Campina Grande (*Unidade Acadêmica de Engenharia de Materiais*) , [4]Universidade Federal da Paraíba, [5]Federal University of Paraíba (*Department of Renewable Energy Engineering*)

e-mail: isaacmoura@cear.ufpb.br

Repurposing, repairing or recycling can return materials to active use, creating a technology cycle [1]. Thus, the objective of this work was to produce a biodegradable compound from waste from paper and coconut fiber to be used in the cultivation of seedlings, replacing plastic materials that contribute to the increase in garbage. Paper, coconut fiber (Cocos nucifera) and a gum-based glue were used as raw materials. The biodegradable compound underwent physical-chemical characterization and UV-Vis spectroscopy. The physical-chemical analytical result of the material confirmed the release of elements considered essential for the development of the plant, such as Ca, N, P, K, Mg, Fe, Cu, among others. From the UV-Vis spectra, two significant absorption peaks of 0.81 and 0.87 were identified at wavelengths 257 and 307 nm, respectively. Absorption events in this range probably occurred because it is a lignocellulosic material.

The absorption of radiation is important for plants, however, when subjected to large exposures, it may harm the development of the plant. In general, a biodegradable compound absorbs less. Based on the excellent results obtained, it is concluded that the development of the biodegradable compound contributes significantly to the environment, replacing plastic bags.

e-mail: barnez164@gmail.com

Poly (vinyl chloride) (PVC) is commonly used to manufacture biomedical devices and hospital components, but it does not present antimicrobial activity enough to prevent biofouling. With the emergence of new microorganisms and viruses, such as Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) that was responsible for the global pandemic caused by Coronavirus Disease 2019 (COVID-19), it is evident the importance of the development of self-disinfectant PVC for hospital environments and medical clinics where infected people remain for a long time. In this contribution, silver nanoparticles (AgNPs) were incorporated into poly(vinyl chloride) (PVC) by melt mixing method. PVC nanocomposites containing Ag/SiO2, Ag/SiO2/ZnO and AgNPs in colloidal suspension (SC-AgNP) were prepared, and their properties were characterized by several techniques as Fourier-transform infrared absorption spectroscopy (FTIR), Thermogravimetric analysis (TGA), Scanning electron microscopy (SEM), Uniaxial tensile tests, Impact tests and antibacterial tests. The results obtained showed the presence of organic compounds in Ag/SiO2/ZnO and SC-AgNP additives. Regarding the morphology of the nanocomposites, there was low adhesion between matrix and reinforcement and a tendency for the Ag/SiO2 and SC-AgNP particles to agglomerate. The best dispersion of the particles occurred in the nanocomposites with Ag/SiO2/ZnO. The mechanical properties of PVC were altered in the presence of the nanoparticles by the low adhesion with the matrix and the influence of the additives on the crystallinity of the polymer. In general, the nanocomposites developed are promising for obtaining materials with antibacterial and mechanical properties.

Study of coating mortars with reuse of rubber wastefrom the tire retreading process

e-mail: leticia.pagoto@unesp.br

Abstract: The consumption of non-renewable natural resources in the civil construction industry is an issue that has led researchers to seek sustainable alternatives. The tire retreading process generates waste that can be reused in mortars. Therefore, the objective of this work is to experimentally evaluate coating mortars produced with partial replacement, in volume, of sand by tire retreading rubber (passing the #1.19 mm sieve), in variations of 5% and 10% (AB5 and AB10, respectively), compared to the reference composite, without incorporation of rubber (AB0). For this, consistency, mass density in the fresh state, incorporated air content, mass density in the hardened state and water absorption by capillarity were carried out. The results showed that the incorporation of rubber reduced the consistency index, but did not affect the workability. The mass density, in the fresh and hardened state, also decreased, reaching a reduction of 4.2% for AB10 in relation to the reference, in the hardened state, and this is due to the lower unit mass of rubber in relation to sand and the increase of the entrained air content. The capillary coefficient of composite AB5 remained practically equal to AB0, while for AB10 there was a more significant reduction of 15% in relation to AB0. Therefore, it is concluded that the use of retreading rubber in mortars can be a sustainable alternative in coating mortars.

e-mail: mayconericles.ufpi@gmail.com

Abstract

In this study, Ti-35Nb-7Zr-5Ta alloys were coated with hydroxyapatite and iron oxide in order to investigate the electrical conductivity of the samples due to the presence of iron [1]. For this, samples containing hydroxyapatite and iron oxide in different concentrations were prepared. The deposition was performed by the biomimetic method [2]. The samples were characterized by: Scanning Electron Microscopy (SEM), Raman Spectroscopy, Energy Dispersion X-Ray Spectroscopy (EDS), X-Ray Diffraction (DRX) and by the Four Point Probe. Scanning electron microscopy allowed a detailed visualization of the morphology, while X-ray diffraction and Raman spectroscopy were used respectively to study the crystalline structure and chemical composition of the samples [3]. The four-pin probe was used as an essential tool in this study to directly measure the electrical conductivity of the produced samples. The variation in iron concentration in the samples was one of the main objectives of the research, and the four-point probe made it possible to accurately assess the effect of this variation on the electrical conductivity of the samples.

Synthesis and characterization of composite obtainedby combining conjugated polymer poly(p-anisidine) with Au nanoparticles

Diogo de Carvalho Menezes[1], Edgar Aparecido Sanches[2], Yvonne Primerano Mascarenhas[3]

[1]Escola de Engenharia de São Carlos (USP), [2]Universidade Federal do Amazonas, [3]Instituto de Física de São Carlos- USP

e-mail: diogo.menezes@usp.br

Standard chemical oxidative polymerization of p-anisidine was performed. Solution I was prepared by solubilizing 2.0 g of p-anisidine monomer in HCl 1M, and Solution II was obtained by adding 4.0 g of ammonium persulfate also in HCl 1M. Solution II was incorporated dropwise to Solution I under constant stirring. After 3 hours, the dark powder was vacuum filtered, washed, and kept in a desiccator until reached constant weight. For the composite synthesis, the same method as described above was performed to obtain PPA/AuNP but incorporating 10 ml of gold nanoparticle dispersion (AuNP) to Solution I. X-ray powder diffraction was obtained with CuKα radiation, 40 kV, and 20 mA. The scan mode was performed with 0.02°/s step, velocity of 5°/min, in the $2\theta = 3 - 73°$ interval. The XRDpattern of PPA showed a broad halo, between $2\theta = 15°$ and 34°, and centered at $2\theta = 24.5°$, due to the polymer amorphous phase, a strong peak at $2\theta = 5.2o$ and some small, superimposed peaks indicated some crystallinity [1]. Similar pattern was obtained to PPA/AuNP yet exhibiting a smoother halo, indicating some crystallinity improvement. Characteristic XRD patterns corresponding to gold nanoparticles confirm the occurrence ofboth phases in the composite material. With higher crystallinity percentages, we expect toget properties, in general, enhanced for overall applications. Thermogravimetric (TG) analysis already indicates improvement in thermal stability among the composite form.

Synthesis and characterization of PEO-PPO based polyureas for pharmaceutical drug delivery applications.

Heber Eduardo Andrada[1], Júlia Gabriela Matos Vargas[1], Bruno Andrade Fico[1], Julia Mirian Paulino[1], Natalia Nascimento Silveira[1], Raquel Alves Dos Santos[1], Eduardo Ferreira Molina[1]

e-mail: heberandrada@hotmail.es

Controlled drug delivery involves the sustained release of bioactive molecules over a given period of time. In this sense, polyurea matrices based on polyetheramine-isocyanates present interesting (physical and chemical) properties for use as drug delivery systems. Polyureas are obtained from the reaction between a polyisocyanate and a polyamine to form urea groups that can interact via hydrogen bonds [1]. To evaluate possible structural changes and thermal stability of the polyurea, polyetheramine-based polyurea networks were synthesised with polypropylene oxide (PPO) or polyethylene oxide (PEO) and hexamethylene diisocyanate-HDI trimer [2]. The network formation was controlled by sol- gel reactions, and the obtained materials were characterised by different techniques (FTIR,XRD, XRD, TGA). Furthermore, it was possible to modulate the amount of diclofenac released as a function of time by studying the water absorption or swelling capacity, cytotoxicity and toxicity. The release profile was then correlated with the water absorptionby the PEO/PPO polyurea matrix (of similar molecular weight), and the release profile wasanalysed with the water absorption by the PEO/PPO polyurea matrix [3]. Finally, links couldbe established between diclofenac release and properties of the polyurea matrices, such aswater absorption capacity. Our aim here is to identify challenges and opportunities for thedevelopment of innovative functional biomaterials for healthcare applications.

The increased use of the herbicide diuron for weed management is a contributing factor to its environmental release, leading to the contamination of drinking water sources. Given its persistence in the environment and harmful impacts on human health, monitoring both in the environment and in food is crucial.[1] The purpose of this work was to synthe a bifunctional hybrid organic-inorganic molecularly imprinted polymer (BHMIP) by the sol-gel process and free radical polymerization for the quantification of diuron in aqueous and food matrices. The polymer was synthed using methacrylic acid and phenyltrimethoxysilane as organic and inorganic functional monomers, respectively. The BHMIP was characterized by means of MET, SEM, FTIR, X-ray photoelectron spectroscopy, and TG. The printed polymer was used as an adsorbent for solid phase extraction (MISPE), in the development of a chromatographic method (HPLC-DAD) of preconcentration of diuron, whose optimized conditions were: 150.0 mg of mass of PHB-MIP filled in the SPE cartridge, preconcentration volume (pH 4.0) of 50.0 mL and 6.0 mL methanol as eluting solvent. The MISPE method showed a linear range of 0.27 to 200.0 µg L-1, a high pre-concentration factor, evaluated at 173, with a max adsorption capacity of 140.1 mg g-1. The LOD achieved was 0.08 µg L-1. The proposed method was applied to samples of water and soy milk. Samples were enriched with diuron and satisfactory recovery percentages were achieved (91 to 104% and 93 to 110%, respectively). Given the results obtained, using two functional monomers ensured high adsorptive capacity and selectivity to the material. It was also possible to apply it to environmental and food samples without matrix effect.

Bacterial cellulose (BC) is a biopolymer, which can be obtained from renewable sources. It is biocompatible and has good mechanical properties. Much researchs has focused on BC for applications biomedicals, food packaging, water purification and conductive composites [1]. Among the conductive polymers, polyaniline (PAni) has gained prominence due to its good electrical conductivity, good chemical stability and ease of synthesis, however, it has low mechanical strength [2]. Therefore, the combination of PAni properties in a CB matrix results in a polymeric film, flexible, porous and conductive. In this work, was used a new route for preparing conductive composites based on polyaniline and bacterial cellulose, obtained by conventional method [3] and an alternative method. Were compared and evaluated through the analysis of conductivity by the four-point probe method, impedance and cyclic voltammetry. The results of DRX, UV-Vis and Raman, indicate that these composites presented structural characteristics, according to the literature. Too, they presented conductivity, identified by means of a multimeter. Therefore, it is believed that these materials can have the potential for applications such as electromagnetic interference shielding flexible electrodes for electrochemical sensor and supercapacitors.

Currently the bio-based products industry is ineffective in using lignins as a resource for sustainable and circular materials. Thus, a promising application of kraft lignin (KL) is to use it as a carbon source to produce carbon foams (CF). CF are materials with a pore structure, formed mainly of macro-pores that bond together, generating materials with light relative density and high electrical and thermal conductivity. The additivation with graphene oxide (OG) and its reduced form (rGO) is a promising branch since they are carbon-based nanomaterials with unique physical and chemical properties, such as high surface area and mechanical strength that allow various applications such as supercapacitors, sensors, filters, among others. In this work, the soluble fraction of KL was used as a partial substitute for phenol in phenolic resins, added with 1, 2 and 4% GO and rGO to prepare CF, using polyurethane foams as sacrificial mold. The obtained CF were studied for application in electrochemical sensors. The CF were ground and sieved, and then the powder obtained was adhered to the surface of a conductive substrate. For this, an electrochemical study was performed using the techniques of cyclic voltammetry (CV) and electrochemical impedance spectroscopy (EIS), to verify the trend of the current density (J) and the values of the charge transfer resistance (Rct). The samples that showed the best J and Rct results were GO2% and rGO2%, which is the best percentage of additivation, however all CF produced showed electrochemical response and potential application as sensors.

Synthesis of PMAEMA copolymers for antimicrobial materials

Liliam Carmo de Castro[1], Gustavo Galhano Vieira Galvão[2], Cauã Veloso da Silva[2], Fabio Herbst Florenzano[3]

[1]Escola de Engenharia de Lorena - EEL/USP (*Departamento de Engenharia de Materiais*) , [2]Escola de Engenharia de Lorena - EEL/USP, [3]Escola de Engenharia de Lorena - Universidade de São Paulo (*Departamento de Engenharia de Materiais*)

e-mail: liliamcarmo@usp.br

The synthesis of antimicrobial polymers has attracted great interest lately, particularly for coating of different surfaces in order to avoid the dissemination of viruses and bacteria.[1,2] The objective of this work is to synthe materials via RAFT, seeking to study their antimicrobial performance accordingly to their composition and molar mass.[3] Two syntheses of copolymers were performed by RAFT, varying percentage compositions (50%DMAEMA:50%MMA and 30%DMAEMA:70%MMA). The use of a RDRP technique is mandatory in this kind of approach to guarantee interchain composition homogeneity. Molar mass monitoring was performed by Gel Permeation Chromatography (GPC), demonstratinga kinetic pattern compatible with controlled polymerization for both materials. The copolymer with equimolar percentage proportion presented a slower rate of polymerization at the beginning of the reaction. The two purified materials had polydispersity index below 1.5 and were characterized by FTIR. The materials are to be tested for the antibacterial activity in order to study the influence of PDMAEMA composition.

Anthocyanins (ACN) make up the largest group of water-soluble pigments in the plant kingdom. However, they have a disadvantage compared to synthetic dyes due to the change in color during the processing and storage of the material. One of the strategies to improve the stability of ACN is the production of hybrid ACN pigments with clay minerals. The present work aims to produce hybrid pigments based on Bentonite (Bent) intercalated with cetyltrimethylammonium bromide (CTAB) and anthocyanin dye (ACN). The hybrid pigments were characterized by X-ray diffraction (XRD), infrared spectroscopy (FTIR), and scanning electron microscopy (SEM).the hybrid pigments based on the natural dye anthocyanin and the clay mineral bentonite were obtained, in which the influence of the amount of CTAB introduced in the previous modification of the clay mineral was evaluated. In addition, DRX, FTIR, and SEM characterization techniques proved that organic molecules were intercalated between the mineral layers of the clay while producing the hybrid pigments

Thermal and mechanical evaluation of adobesreinforced with coconut fibers

Jenifer Tejada Cardoso[1], Ricardo Ferrari Ferraz[1], Thaís M. T. Nascimento[1], Raquel A. P. Oliveira[1], Tainara Tejada Camacho[1]

[1]UNIVERSIDADE FEDERAL DO VALE DO SÃO FRANCISCO (*Pós-graduação em Ciência dos Materiais*)

e-mail: jenifer.tejada@discente.univasf.edu.br

Adobe is an unburned brick to which stabilizers are commonly added to improve its mechanical characteristics. The main objective of this work is to evaluate the impact of coconut fibers addition on the mechanical and thermal performance of the manufactured adobes. To do this, the soil was initially characterized by means of a granulometric test. Then, the morphology of the coconut fibers was evaluated by scanning electron microscopy (SEM). For the structural characterization, soil and fiber samples were subjected to X-ray diffraction (XRD) technique. Furthermore, in order to determine the chemical composition of the raw materials, an evaluation was carried out using the Fourier transform infrared spectroscopy technique (FTIR). After that, it was determined which compositions of adobes would be studied: M1 (reference, without fiber addition), M2 (addition of 0.25% w/w of fibers with 5 cm), M3 (0.50% w/w of fibers with 5 cm), M4 (addition of 0.25% w/w of fibers with 2.5 cm) and M5 (addition of 0.50% w/w of fibers with 2.5 cm). The adobes were also evaluated in terms of their mechanical strength, by means of compression test, and thermally, using the heat flow method. The results of the granulometry define the soil as loamy-sandy-clayey. For the fibers, SEM showed their rough nature. In addition, the experimental powder pattern of the soil confirmed the presence of silicon oxide (SiO_2), reference ICSD 089277, in its composition. XRD analysis of the fibers revealed the semi-crystalline nature of this material. Furthermore, when comparing the strengths of the adobes, better results were obtained for batch M4 (average of 1.89 MPa) and worse for batch M3 (average of 1.31 MPa). In the thermal evaluation, batch M5 stood out, with a thermal damping of 59.39%. Thus, the results showed an improvement in the thermal and mechanical properties of adobes with the addition of coconut fibers.

Thermal, optical and morphological properties of PVA/chitosan blend incorporated with parsley extract

Érica dos Santos Ribeiro[1], Elaine Nascimento Aquino[2], Artemis Marti Ceschin[3], Nizamara Simenremis Pereira[1]

[1]Instituto Federal de Brasília (*Química*) , [2]Instituto Federal de Brasília, [3]Univesidade deBrasília (*Engenharia Elétrica*)

e-mail: ericasantosribeiroo@gmail.com

Nowadays, research on active packaging includes the incorporation of natural active substances with antioxidant properties and antimicrobial activity [1]. In this work, a mixture of the equal volumes of the PVA prepared polymer blends of polyvinylalcohol (PVA), chitosan (CH) and parsley extract (PE) and CH solution kept under stirring for 1h. Then, a volume of parsley extract required to produce PVA/CH films with 8 and 16% extract was added. The mixture was transferred to a non-stick surface and taken to the oven for 19 h at ≈50 °C. UV-VIS spectroscopy revealed that the incorporation of PE into the PVA/CH matrix promotedthe shift of the main band of the host matrix. The photoluminescence (PL) of the parsley extract as well as the PVA/CH/PE film, when excited at 450 nm, showed a band in the rangeof 460 to 620 nm with a maximum at 522 nm, while the pure PVA/CH film showed noluminescence in this region of the spectrum. Using a □exc at 300 nm, the parsley extractshowed an emission band at 408 nm, while the PVA/CH/PE film showed an emission with amaximum at 390 nm. At this □exc (300 nm), pure PVA/CH blend showed the same emissionspectrum as the blend incorporated with PE. Thermal analysis showed that parsley extract is easily thermally degraded. The PVA/CH/PE films showed four phases of degradation ThePE extract does not change the thermal stability of the blend. Scanning electron microscopy(SEM) of the surface of the 8% PVA/CH/PE film showed smoothies with small well-scatteredholes. However, micrographs of PVA/CH/PE 16% revealed different morphology with the assigned groove in specific circular regions. The internal morphology of the 8% PVA/CH/PEblend confirmed the existence of circular holes, while the 16% PVA/CH/PE blend had a smooth surface.

The present work studied the synthesis, characterization and functionalization of magnetic nanoparticles and magnetic nanocomposites based on iron oxide functionalized with soybean oil-based biopolymer, (BPLMR), with the purpose of environmental remediation (adsorption studies) of organic compounds in aqueous solution, such as rhodamine B (Rh B) [1]. The biopolymers associated with magnetic nanoparticles have several advantages, such as good surface area [2], magnetic properties that aids in the recovery of the adsorbent, among others. Nanoparticles have been used for the adsorption of organic compounds and metal ions with considered adsorptive efficiency [3]. In this regard, strategies to obtain stabilized nanomaterials in solution is very important as they can improve colloidal stability and surface properties such as adsorption. The synthesis of nanoparticles was be performed by the co-precipitation method and for the characterization of these nanostructures, scanning electron microscopy (SEM) and transmission electron microscopy (TEM), X-ray diffractometry (XRD), Fourier transform infrared spectroscopy (FTIR), kinetic and thermodynamic study and UV/Vis spectroscopy analysis will be used the obtained results will be compared in the literature with functionalized Fe3O4-based nanoparticles and other nanoparticles.

Thermo-optical properties of PVA films doped with carbon dots

Lavínia Malta Braga[1], Italo Marcos Nunes de Oliveira[2], Raul Lima Ferreira[3]

[1]Universidade Federal de Alagoas (*Instituto de Física*) , [2]Universidade Federal de Alagoas (*Física*) , [3]Universidade Federal de Alagoas

e-mail: lavinia.malta@fis.ufal.br

Polyvinyl alcohol (PVA) is a water-soluble polymer that presents biocompatibility and biodegradability, being widely used for clinical applications, production of films, fibers, and materials packaging. Moreover, a remarkable amount of attention has been devoted to PVA due to its transparency, film-forming capability, mechanical rigidity and high chemical resistance. Recently, the application potential of this polymer has been demonstrated in electro-optical devices and flexible solar cells. Several studies have been carried out focusing on the doping of PVA films with nanomaterials, in particular, with carbon quantum dots. Some studies have shown that the addition of these nanoparticles improves the mechanical and optical properties of PVA films. In this study, the spectroscopic and photothermal properties of polyvinyl alcohol polymeric films, doped with carbon quantum dots derived from methyl red azo dye, are investigated. The impacts of nanoparticles addition into the polymer matrix are explored, with emphasis on absorption and emission spectra, FTIR and lifetime measurements. Using time-resolved Z-scan measurements, it is investigated how film doping modifies the thermo-optical response of these materials. From the thermal lens model, it is investigated how the concentration of carbon quantum dots affect the thermal diffusivity and the thermo-optical coefficient of PVA films. Thermal effects on fluorescent properties of PVA - CD-MR composite are analyzed.

THE ROLE OF CYSTAMINE DIHYDROCHLORIDE MEDIATING REDOX-SENSITIVE GELATIN NANOHYDROGELS

Cancer is the second leading cause of death worldwide after cardiovascular disease, according to the World Health Organization [1]. Aside from mortality, the economic impact has grown year after year due to rising medical and hospitalization costs. As a result, new medical devices to reduce or even treat cancer are required. In this study, gelatin was derivatized by maleic anhydride to produce nanohydrogels. With a grafting degree of 45%, the derivatization steps anchored maleimide groups onto the gelatin backbone. A Michael-addition reaction between gelatin maleimide groups and cystamine dihydrochloride amine groups crosslinked the derivatized gelatin. In addition, the hydrophilic and lipophilic balance was adjusted to improve drug uptake and release A disulfide linkage in the cystamine molecule demonstrates sensitive responsiveness to reduced glutathione expressed in cancer cells [2]. Derivatized gelatin was crosslinked in an inverse emulsion system, where particles with hydrodynamic diameters ranging from 200 to 400 nm were obtained. Sodium diclofenac was used as a drug model. The structure of nanohydrogels was evaluated during the release step and the value of hydrodynamic radius and gyration radius were compared as a function time. The gelatin nanohydrogels produced have the potential to be used as a drug delivery system.Acknowledgments:CAPES, CNPq and, IQ UNESP.References:[1]. ORGANIZATION WH. Twaron® fabrics impregnated with fluid and shear thickening gels (STF and STG) - applications forballistic vests

Dayanne dos Santos Silva[1], Maria de Fátima Vieira Marques[2], Ludmila da Silva Candido[3], Maurício Ferrapontoff Lemos[4]

[1]Universidade Federal do Rio de Janeiro (*Instituto de Macromoléculas Professora Eloisa Mano*) , [2]Universidade Federal do Rio de Janeiro, [3]Universidade Federal do Rio de Janeiro (*Instituto de Macromoléculas Professora Eloísa Mano*) , [4]Instituto de Pesquisas da Marinha

e-mail: dayanne.santos@ima.ufrj.br

Several studies are being developed to achieve flexibility without compromising the performance of ballistic vests using other materials in conjunction with p-aramid fabrics. The so-called "liquid armor" stands out. This type of armature consists of fluids or gels with non-Newtonian behavior, which, under normal conditions, are flexible. However, the viscosity increases when subjected to mechanical disturbances capable of exceeding a critical shear rate value. The fluid or gel ceases to be liquid/thick and starts to have the characteristics of rigid materials, thus protecting the vest from being penetrated by the projectile[1]. In the present work, composites were produced with three layers of p-aramid fabrics impregnated with shear-thickening fluids and gels (STF and STG), which were prepared based on polyethylene glycol (PEG 200), hydroxylated liquid polybutadiene (PBLH) and nanoparticles of silica ($SiO2$), zinc oxide (ZnO) or boron carbide ($B4C$). It is important to note that synthed gels based on polyurethanes are unprecedented for such applications. The results showed that the thermal cross-linking reaction increased the hydrophobicity of the PBLH gels, confirmed by the contact angle test. The ballistic tests showed that the friction between the yarns increased after the impregnations, changing the failure mode of the fabrics from deformation in pure yarns to fiber breakage in treated fabrics.

Furthermore, it was noted that impregnated fabrics achieved better ballistic resistance through increased impact energy absorption. Comparing STF and STGs of both polymers, it was evidenced that the PBLH performed better. The fabrics impregnated with polyurethane gels with the addition of B4C nanoparticles proved promising for application in ballistic fabrics.

Use of Carbon Nanofibers in UHMWPE/PEG Blend:Analysis of Morphological and Mechanical Properties

Johnnys da Silva Hortencio[1], Fabiana de Carvalho Fim[1], Lucineide Balbino Silva[1]

[1]Universidade Federal da Paraíba (*Departamento de Engenharia de Materiais*)

e-mail: johnnyshortencio@outlook.com

The preparation of polymeric nanocomposites with fillers has been a way to obtain materials that help to improve the performance of polymeric materials. Nanofillers have emerged with great potential for use in polymeric nanocomposites, mainly due to their mechanical and thermal properties [1]. In this work, polymeric nanocomposites with carbon nanofibers (CNF) were prepared by grinding the powders in order to evaluate the modifications promoted by the incorporation of CNFs in the matrix of a UHMWPE /PEG blend through the morphological and mechanical properties. Grinding was carried out in a pitcher mill with concentrations of 0.5; 1.0 and 1.5% (w/w) CNF for a 24 hour period. All samples were characterized by scanning electron microscopy (SEM) and mechanical tensile tests. Regarding the mechanical properties of the nanocomposites, the CNFs were not efficient, causing a decrease in the properties of the UHMWPE /PEG blend due to the dispersion and distribution of the fibers not being efficient. The SEM images showed the formation of clusters of CNFs in the blend matrix, which caused a decrease in Young's modulus and tensile strength. On the other hand, there was an increase in the ductility of the blend as the amount of CNF in the blend matrix increased [2,3].

e-mail: bianca.menezes@unesp.br

Abstract: In order to analyze the potential of the thermographic technique, a simulation of real conditions of accidental humidity was carried out in mortar test specimens, differentiated by coatings of ceramic plates, plaster, stone and mortar. Two evaluation and identification techniques were used, with a common parameter: temperature. The techniques, passive and active, are extreme in the induction or not of heat transfer to the prototypes, monitoring in a methodological process of time, temperature and emissivity with the resource of capturing images of visible light with the thermographic camera. Based on the development of the study, the results and discussions were partial to what was expected, since the object of study being at a higher temperature, that is, during the active test, the temperature difference was more clearly visible, which facilitated the detection of moisture, however, in coatings such as natural stone and ceramic tiles, the techniques were not very effective. Therefore, the color gradient has a positive influence on the final result and all the necessary procedures and parameters, in addition to physical characteristics, directly influence the achievement of results, based, in particular, on identifying the pathological manifestation studied, differentiating the results by method passive and active.

Gas sensors employing nanocrystal/cluster modified graphene

Eduard Llobet[1], Juan Casanova[2]

[1]Universitat Rovira i Virgili (*Electronic Engineering*) , [2]Universitat Rovira i Virgili

e-mail: eduard.llobet@urv.cat

The release of harmful gases into the atmosphere, is becoming a major societal concern due to its effects on human health and the environment. While graphene has emerged as a promising material for developing room temperature operated gas sensors, its inertness and lack of specificity results in low sensitive and poorly selective devices. This lecture addresses several approaches for overcoming the drawbacks mentioned. These consist of loading graphene with polymer nanoparticles, metal clusters or perovskite nanocrystals, thus tuning their gas sensing properties. The synthesis, characterization, sensing properties and sensing mechanisms will be presented and discussed in detail. Additionally, reliability and long-term stability aspects will be dealt with as well.

e-mail: c.blackman@ucl.ac.uk

Conductometric gas sensors (CGS) provide a reproducible gas response at a low cost but their operation mechanisms are still not fully understood. Using synchrotron radiation, we investigated a working SnO_2sensor under operando conditions via near-ambient pressure (NAP) XPS with simultaneous resistance measurements, and created a depth profile of the variable near-surface stoichiometry of SnO_{2-x}as a function of O_2pressure. Our results reveala correlation between the dynamically changing surface oxygen vacancies and the resistance response in SnO_2-based CGS. While oxygen adsorbates were observed in this study we conclude that these are an intermediary in oxygen transport between the gas phase and the lattice, and that surface oxygen vacancies, not the observed oxygen adsorbates, are central to response generation in SnO_2-based gas sensors.

Wearable sensors and biosensors for monitoring health and food quality

Osvaldo Novais de Oliveira Junior[1]

[1]Universidade de São Paulo

e-mail: chu@ifsc.usp.br

The concepts of personalized medicine and precision agriculture have gained momentum with a number of technologies based on wearable sensors and biosensors that can be used to monitor health conditions, and water and food quality at the point of use. Because the principles of detection and the synergy achieved in combining nanomaterials and biomolecules are common to all of these technologies, a single platform can be establishedin spite of the variety of materials employed and of the distinct targeted applications. In this lecture, examples will be given of wearable electrochemical biosensors to monitor the concentrations of urea in sweat and of glucose in urine. In both cases, the cost of each sensing unit is very low and the measurements are performed with portable devices, thus allowing for point-of-care diagnosis. Also discussed will be electrochemical paper sensors for non-destructive routine analysis of pesticides on plants, fruits, and vegetables, which can be performed over the entire food processing chain, from the farms up to the industry and supermarkets. A key feature in this sensing platform is the ability to control the molecular architecture in the biosensors which are made essentially of layered nanometric films. The large of amount data generated while monitoring the different markers and contaminants are now routinely analyzed using machine learning approaches, with which efficient intelligent systems can be built.

Working towards sensing at room temperature with carbon nanotubes

Paola Ayala[1]

[1]Universität Wien (*Physics*)

e-mail: paola.ayala@univie.ac.at

The electronic and optical properties of carbon nanotubes are very sensitive to the chemical environments. It is therefore inferable why they are so attractive as sensing objects. These one-dimensional nanostructured materials have been the focus of intensive research but it is important to keep in mind that practical difficulties to produce them ultra-clean and nearly defect-free have constantly appeared as stumbling blocks for their use in applications controllably and reproducibly. One of our pilot experiments -to understand how the intrinsic properties of single-walled carbon nanotubes vary when they are exposed to gases- was to investigate the adsorption of O_2, NO and NO_2molecules. We performed experiments on ultra-pure nanotube material and then tested the influence of molecular fillers. Strikingly, we figured out that many of the sensing effects that had been reported previously were produced in great part by the presence of impurities and defects. This affects tremendously the reproducibility of the experiments. We have also shed light on the nature of adsorption and its effect on their electronic properties of the tubes. Metallicity-sorting and the further use of carbon nanotube hybrids are able to unfold two major challenges: tuning the gas-tube interaction and achieving desorption of gases at ambient temperature. A result to highlight was that using time resolved photoemission we observed that in semiconducting nanotube hosts the chemical potential is pinned inside their energy gap shifted to the onset of the conduction band when nanotubes filled with nanoclusters are used. This remarkably reveals that having a metal cluster filling could represent a key to high sensitivity with a very effective desorption at ambient temperature. I will present an overview of my group's related research.

Affordable Materials and Methods for Acoustofluidic Device Fabrication

Giclênio Cavalcante da Silva[1,2], José Nathan Holanda Madeiros[2], Glauber T. Silva[1]

[1]Federal University of Alagoas (*Physical Acoustics Group*), [2]Integrated Acoustofluidics Laboratory LTDA

e-mail: gicleniocs@gmail.com

Acoustofluidic devices are becoming increasingly popular due to their precision and efficiency in manipulating fluids and particles at micro/nanoscale. However, their widespread use is limited by the high cost of traditional fabrication methods. In this talk, we introduce a new approach for the fabrication of acoustofluidic devices using affordable materials and methods such as 3D printing, laser cutting of glass, and double-sided tape. We showcase the feasibility of this approach by creating a range of devices, including standing-wave resonant devices. Our devices have potential applications in medical diagnosis and live-cell monitoring. For example, using our standing-wave device, we were able to perform immunoagglutination tests with high precision and accuracy for various analytes, including bacteria, viruses, and proteins. This is important for early disease diagnosis, where low concentrations of analytes must be detected in complex biological samples. Additionally, we can use our devices for live-cell Raman spectroscopy, which provides valuable information about the chemical composition of living cells. Unlike conventional Raman methods, our approach enables non-contact and non-invasive manipulation and trapping of individual cells, allowing high-sensitivity and high-selectivity live-cell Raman spectroscopy. This is particularly important for studying cellular processes and the effects of external stimuli on cell metabolism. Our approach provides a low-cost and easy-to-implement solution for fabricating acoustofluidic devices with high precision and accuracy. This makes it a promising platform for the development of novel diagnostic and analytical tools.

e-mail: nicola.daldosso@univr.it

Zeolites are crystalline porous materials with significant applications in greenhouse gas capture like $CO_2$and NO_x, heavy metals, hydrocarbons and other dangerous contaminants for the environment. Moreover, the porous crystalline nature of zeolites allows a homogeneous dispersion of luminescent species, which could add sensing functionality to the material. Rare earth ions (RE^{3+}) are particularly interesting for this scope because their photoluminescence (PL) emissions have a clear and identifiable spectral shape and long luminescence lifetimes. Among them, Eu^{3+}emission in the red is sensitive to the surrounding environment, potentially responding to the absorption or desorption of contaminant species. In this work, two different commercial zeolites (5A and 13X) were doped by Eu^{3+}ions and Ag aggregates via ion-exchange in solution. Ag can provide a significant increase of the Eu^{3+}PL intensity and a widening of the excitation band, as well as an additional blue emission. Optimization of the synthesis process supported by a detailed structural and optical characterization as well as preliminary testing on the sensing capabilities will be presented.

Carbon Dots from Cysteine for pH sensing, CMCdetection and cellular imaging applications.

Carbon quantum dots (CDs) have emerged as promising nanomaterials in several scientific fields due to their small, low cytotoxicity, luminescent properties, ease of synthesis, and water solubility. Their fluorescence property is the most significant and contributed to their discovery. In this work a simple synthesis was presented, through the hydrothermal synthesis process, using cysteine as a precursor material, which results in CDs self-doped with oxygen, nitrogen, and sulfur (cys-CDs), adapted from Zhang et al. [1]. Subsequently, sensitivity was characterized and evaluated against different pHs, showing an efficient sensitivity between pHs 2 to 9, with application in real samples, and promoting control of its luminescent properties. This variation was characterized, showing a change not only in the intensity but also in the emission wavelength of the luminescence. Using various techniques, we were able to understand the causes of this effect. Rapid test devices were successfully developed for water pH analysis, as well as for the production of ink anticounterfeiting CDs [2]. The CDs derived from cysteine also were employed as a potential probe for identifying critical micellar concentrations (CMCs) of surfactants. This approach demonstrated a simple and effective technique for CMC detection. In addition, our research group conducted an investigation into the impact of solid-state thermic treatment (STT) at temperatures ranging from 303 K to 453 K on the, surface characteristics, fluorescence properties, and cellular cytotoxicity of cys-CDs. The findings of our study highlight that a simple post-synthesis treatment can effectively modify the properties of cys-CDs, making them suitable for cellular applications [3]. e-mail: vanessa.abrantes@ufca.edu.br

Fungal lectins are biomaterials with great biotechnological potential, but limited knowledge about their biochemical and biophysical features prevents their proper use [1]. In this work, we evaluated the *Ganoderma applanatum* lectin (GAL) as a glucose biorecognition element at sub-nanomolar levels, using artificial intelligence and electrochemical data from a homologous agglutinin to build the working reaction interface. Materials with glucose affinity are very important to identify and manage this carbohydrate in matrices where its content is critical. Biochemical tests indicated that GAL has moderate resistance to pH (4-8) and temperature (20-60 °C) changes, with its hemagglutinating activity (376.5 HU mg -1 GAL at 20 °C) better conserved at pH ≈ 7.0 / 20 °C. Seeking to offer biocompatibility and favorable electrostatic conditions, GAL was immobilized on Prussian blue-modified glassy carbon electrode, after thermal activation of the metal-complex film. The biosensor developed, henceforth called GAL/ta-PB/GCE, showed a sigmoidal response to increasing glucose concentration, which was well-fitted by the Hill equation, allowing detect it through highly stable and precise electrochemical responses (detection limit = 10.2 pmol L^{-1}; sensitivity = 0.012 $\mu A\ \mu M^{-1} cm^{-2}$). As proof of the platform's usefulness to analyze glucose in complex samples, GAL/ta-PB/GCE was successful tested to quantify it in pharmaceutical formulations, reiterating that the association between different (bio)materials, as well as the combination between theoretical and experimental data, drives important improvements in bioelectrochemical investigations performed at molecular levels.

e-mail: lucianadtrino@gmail.com

A novel label-free electrochemical biosensor based on the zeolitic imidazole framework (ZIF-8) was developed for monitoring protein–protein interactions (PPIs) [1]. The proteinsof interest were ADAM17 and thioredoxin-1 (Trx-1). ADAM17 is considered one of the main proteases responsible for the ectodomain shedding of surface proteins [2] and is mainly associated with pathological processes of diseases [3]. Trx-1 was previously identified by mass spectrometry as an interaction partner of the ADAM17 cytoplasmic domain (ADAM17cyto), which plays a crucial role in the regulation of ADAM17 activity [4]. ZIF-8 was employed as a transducing material and simultaneously carried Trx-1 protein, followed by the deposition of increased concentrations of ADAM17cyto. Structural and morphological characterizations were used to validate and verify the formation of ZIF-8. The interaction between Trx-1 and ADAM17cyto proteins was analyzed through electrochemical impedance spectroscopy (EIS). The results indicate a linear and inverse relationship between the impedance responses at 0.1 Hz for ADAM17cyto concentrations from 0.05 to 8 µM. The proposed biosensor also displayed a significant selectivity and stability verified by using ADAM17cyto mutant and BSA as controls. As a proof-of-concept, we compared the results with a widely used type of PPI assay based on antibody recognition, the solid-phase binding (SPB) assay. The SPB assay was able to detect a significant binding only in ADAM17cyto concentrations above 0.5 µM. The results demonstrate that the developed biosensor was 10× more sensitive and reproducible than the conventional SPB assay, representing a novel strategy for detecting PPIs.

Electrochemical nanoplatform for diagnosis of the schistosomiasis

Sthefany DPaula Elias Torres Gonçalves[1,2], Fábio Lopes de Melo[3,4], César Augusto Souza de Andrade[1,5], Maria Danielly Lima de Oliveira[1,5]

[1]Universidade Federal de Pernambuco, [2]Programa de Pós-Graduação em Inovação Terapêutica, [3]Instituto Aggeu Magalhães, [4]Laboratório de Referência em Esquistossomose, [5]Laboratório de Biodispositivos Nanoestruturados

e-mail: sthefany.torres@ufpe.br

Schistosomiasis is a granulomatous infectious disease, also known as "Bilharziasis", "Xistosis", "Water Belly" and "Snail Disease" [1]. Schistosomiasis is a severely disabling disease that is closely related to poverty and chronic disease [2]. In Brazil, it is caused bythe parasite *Schistosoma mansoni*[3]. When symptomatic, it is a serious disorder in whichthe prognosis largely depends on early diagnosis and treatment. Thus, the development ofnew diagnostic methods for this disease is of fundamental importance. This work aims toprepare and characterize nanostructured films of polypyrrole (PPY) and titanium dioxide nanoparticles (NPsTiO2) deposited on a gold electrode for application as an impedimetric and voltammetric sensor for the detection of schistosomiasis. On the work surface, the electrodeposition of the polypyrrole film was carried out in 12 cycles in a potential range from -0.2 to +0.7 V with a sweep speed of 100 mV.s-1. Then, glutaraldehyde was added to activate the amino groups and, after removing the excess, they were immobilized with NPsTiO2. Finally, the *S. mansoni*probe was immobilized to obtain the PPY-NPsTiO2-Probe*S.mansoni*sensor. Those steps were carried out through electrochemical impedance, which proved the adsorption of the layers by presenting an increase in charge transfer resistance and through cyclic voltammetry, reflected on the variations of the peak currents. Thus, the surface proved to be capable of binding the DNA of *Schistosoma mansoni*.

The development of efficient sensor devices could make air pollution monitoring more accessible and may be vital in accelerating much-needed reductions in air pollution. Gas sensors based on semiconducting metal oxides (SMOx) have drawn attention due to their performance in detecting noxious species. [1,2] The traditional gas sensors commonly work at around 200°C; this high-power consumption needed has become a barrier to their application. Thus, sensing materials working at room temperature are a promising alternative to achieve low-energy consumption. [2] The WO_3 compound has attracted attention as a light-assisted sensing material for detection of a wide range of analytes. Here, we will present an investigation of the microstructural and gas-sensing properties of hierarchical WO_3 nanostructures obtained via aerosol-assisted chemical vapor deposition (AACVD). XRD and FESEM analyses revealed the formation of a monoclinic structure, exhibiting morphology like-rods with dimensions varying between 80 and 400 nm, depending on the AACVD parameters used. Regarding the sensing performance, electrical measurements pointed out that WO_3 nanostructures were sensitive towards sub-ppm NO_2 levels (100 to 1000 ppb) operating at room temperature under continuous blue-light irradiation. Also, the samples were sensitive even under ambient moisture and had a higher response to NO_2 gas compared to the other investigated gases (CO, H_2, and NH_3). The results presented here demonstrate the potential of WO_3 nanostructures as a sensing material operating at room temperature.

Agaricus bisporus lectin/poly(methylene blue)-based photoelectrochemical biosensor for selective lactose analysis in foodstuffs

André Oliveira Santos[1], Vanessa Erika Abrantes Coutinho[1], Heryka Regina Abrantes da Costa[1], Simone Morais[2], Thiago Mielle Brito Ferreira Oliveira[1]

[1]Universidade Federal do Cariri (*Centro de Ciência e Tecnologia*) , [2]Instituto Politécnico do Porto (*REQUIMTE-LAQV*)

e-mail: andrehosantos@gmail.com

Agaricus bisporus mushroom contains a fascinating lectin, here defined as ABL, which has great specificity towards lactose biorecognition [1,2]. In this work, we explored this feature to develop a photoelectrochemical biosensor that recognizes ABL-lactose interactions. Biochemical and biophysical data showed that the macrofungal extract retains lectin activity (640 HU mL^{-1}) even at critical pH values (4-10) and temperatures (20-100 ℃), allowing its direct use as an ABL source. Quantum-chemical simulations and experimental studies revealed favorable electrostatic and biocompatible conditions to immobilize ABL on poly(methylene blue)/fluorine-doped tin oxide-coated glass substrate, resulting in the ABL/PMB/FTO biosensor. In addition to improve conductivity, PMB adds photoactivity (E_{gap} = 1.65 eV) to the device, allowing it to detect lectin-carbohydrate interactions with greater sensitivity under visible light irradiation (470 nm LED). Electrochemical impedance spectroscopy data showed a sigmoidal profile well-fitted by the Hill equation, expanding the working dynamic range (15-540 nmol L^{-1}lactose; LOD = 20.2 pmol L^{-1}) and avoiding laborious sample dilution or pre-concentration steps. Under optimized photoelectrochemical conditions, the ABL/PMB/FTO biosensor showed remarkable signal stability, accuracy, specificity, and selectivity to detect lactose in commercial milk formulations. This work raises even more interest in using fungal lectins as a strategic biomaterial in technologies developed to screen carbohydrates and glycoconjugates in complex samples.

NANOMATERIALS FUNCTIONALIZED WITH GRAPHENE DERIVATIVES FOR BIOSENSORSAPPLICATIONS

Ana Champi[1]

[1]Universidade Federal do ABC (*CCNH*)

e-mail: ana.champi@gmail.com

Nanomaterials such as nanoparticles metallic, magnetic, carbon nanotubes, carbon dots, TiO2 nanotubes, graphene and its derivatives, has shown an easy functionalization with biological molecules such as DNA, enzymes, antibodies, RNA, c-DNA, viruses and bacteriaamong other biological systems generating a wide range of applications in order to developnew disease biosensing devices due to the low cost and speed to obtain results compared toconventional techniques. In this study we report a novel electrochemical portable biosensorfor viruses detection and quantification based on reduced graphene oxide films. The working electrode was built following the synthesis of lysozyme-reduced graphene oxide (rGO) films proposed by Graphene oxide is synthed using modified Hummer's method andchemically reduced using hydrazine and lysozyme[1]. Thin-films were produced by dip- coating deposition using rGO solution onto a gold substrate pre-treated with cysteine. Wereport the successfully application for RNA virus detection using cDNA functionalization onthe working electrode surface and quantification of RNA concentration with a linearly dependency of chronoamperometric current. Also, it shows selectivity against an RNA different from the one used for electrode functionalization. This novel biosensor showed tobe an innovative electrochemical method for in-situ diagnosis of rabies disease in bats witha fast response [2]. This work is grateful to the Fapesp Process : 2020/10567 andCNPq/MCTI/FNDCT 22/2022-Linha 2, Process: 408397/2022-5.

Nosocomial infections and antimicrobial resistance remain recurring problems. Rapid identification of microorganisms is essential to direct immediate treatment and epidemiological control. Electrochemical biosensors identify pathogens and clinically significant biomarkers as an innovative alternative combining nanotechnology with various biorecognition elements such as antimicrobial peptides. The present work aimed to develop an impedimetric biosensor based on multilayer carbon nanotubes and the antimicrobial peptide Temporina-PTA to detect bacteria of clinical interest. Through electrodeposition, the MWCNTs coated the electrode surface with gold. Subsequently, T-PTA was immobilized through coupling agents. The electrochemical impedance spectroscopy technique evaluated the interaction of the sensor platform with bacterial suspensions. Gram-negative and gram-positive bacteria were evaluated. The biosensor presented a detection limit of 10 CFU/mL for all studied species. The analysis time is 5 minutes. Gram-negative species, especially E. coli, obtained the highest impedimetric response. Electrochemical biosensors based on antimicrobial peptides show promise in identifying bacteria, getting results in a few minutes and demonstrating remarkable sensitivity. The developed detection strategy has great potential to help establish technologies to detect pathogens of clinical interest, such as enzymatic and molecular assays.

There is a constant risk of contaminated water with toxic pollutants like heavy metal ions, anions, organic compounds, dyes, lanthanides, gases from anthropogenic and natural activities. Even small amounts of toxic compounds can pose a risk to the environment and human health because they are not biodegradable and bioacumulate. As a result, it is critical to monitor heavy metals in water such as lanthanide ions, but traditional analytical methods are limited due to the cost and needs of large equipment. To address this challenge, it is important to develop an economical, real-time, accurate, and selective detection of toxic pollutants in natural environments. Here, we report three spiropyran derivatives, which were then incorporated into PCL electrospun fibers as a platform for sensing heavy metals in water. The materials obtained were then screened for all lanthanide ions, and the three polymeric systems showed distinct colorimetric responses to different ions, especially Lanthanum and Lutetium. We also demonstrated that it is also possible to selectively identify and differentiate $La^{3+}$and $Lu^{3+}$by emission and naked eye detection. These results showed a promising prospect for portable sensor for field use that may act as colorimetric sensors of toxic heavy metals. Overall, this study demonstrates the potential of spiropyran derivatives as versatile and tunable materials for surface modifications with various applications. Acknowledgements:

This work presents a photopolymerizable printable nanocomposite consisting of a polymeric structural passive phase and a europium complex that acts as a photonically active phase: Eu(btfa)$_3$·bipy@resin. This nanocomposite is being used to produce a printable photonic device that accumulates and reports the dose of UV radiation received by a user, formonitoring their sun exposure as a function of their skin type [1]. Cutaneous production ofvitamin D3 can provide more than 90% of the daily dose, and as it is catalyzed by solar UVBradiation, to monitor the dose received by the user and correlate it with their vitamin D3production, a printed molecular dosimeter was developed here to produce a photonic signalas input for conversion calculations in a software designed to run on a smartphone, [2] forpersonal monitoring of vitamin D3 production. This device was printed in the form of smalldisks using a mask stereolithography 3D printer (MSLA) and the active nanocomposite useda commercial resin with Eu(btfa)$_3$-bipy, exhibiting a well-behaved luminescence quenching related to the absolute UVB dose exposure [3]. The conversions are performed in a smartphone that reads the Eu^{3+}transition peaked at 612 nm ($^5D_0 \rightarrow {}^7F_2$), under a short UVA LED pulse. The thickness of the printed device can be determined as a function of sensitivityand the time of its useful life required for use, resulting in a parameter to be considered inthe dose conversion, together with other parameters associated with the user, such as skintype, age, exposed fraction of the skin, informed in the personal monitoring App.

e-mail: veramarinho34@hotmail.com

Biochar is the product of pyrolysis of renewable biomass, with low oxygen availability. This material is very porous, rich in carbon and contains a large amount of organic structures and inorganic elements. The chemical composition of the ash fraction consists of macro and micronutrients for plants and improves soil fertility conditions. The objective of this research was to carry out the physical-chemical characterization of the cupuaçu bark biochar, identifying its physical properties favorable to its use as a soil conditioner. The cupuaçu peels (Theobroma grandiflorum) used as raw material was purchased from farmersand fairgrounds in the municipality of Parintins. The synthesis of biochar for physical- chemical and morphological characterization was carried out using the activating agent phosphoric acid (H3PO4) in a ratio of 1:1 by mass. The physical and chemical characterization by X-Ray Diffraction Technique (DRX) was performed at Federal Institute of Amazonas, Campus Manaus Centro and the morphological one by Scanning Electron Microscopy (SEM) at INPA''s Optical Microscopy Laboratory. the X-ray diffractograms obtained for the biochar samples synthed at 400°C and 500°C. It is possible to observe thatthe samples have an amorphous structure, characterized by the wide peak in the 2θ positionfrom 5° to 30° C. The amorphous peak is attributed to the presence of carbon. The micrographs of biochar synthed at 400°C and 500°C show the morphology of the material. Itis possible to identify that the surfaces are porous. Figures 2 A and C corresponding to thebiochar synthed at 400°C show larger pores than the biochar synthed at 500°C. It can beconcluded that the lower temperature in the fast pyrolysis influences the formation of largerpores. This may indicate that the raw material of the samples was thermally decomposedduring the pyrolysis process, as expected, and that the obtained biochar has a high capacityfor nutrient and water retention.

Planar vs Non-Planar Orientation in AuAg-Catalyzed InP Nanowire Growth: Implications for Sensing Device Fabrication

The growth of nanowires using metal catalysts presents a challenge for producing devices on a larger scale, especially when integrating III-V nanowires with Si-based electronics. The correct positioning of vertically-grown nanowires on planar electrodes is still a problem if a high yield in device fabrication is required, as we demonstrated in the past with InP biosensors [1]. To address these issues, controlling the orientation of nanowires in or out of the substrate plane using different metal catalysts may be a useful tool. In this study, we investigated InP nanowires catalyzed by Au, Ag, and AuxAg1-x nanoparticles grown on GaAs substrates with varying orientations. Our analysis of experimental data and modeling revealed that the droplet surface density-to-In precursor flux ratio is a crucial parameter in controlling the nanowire growth mode and spatial orientation. These findings offer insight into the vapor-liquid-solid growth of planar nanowires and provide a means of controlling the growth orientation of III-V nanowires catalyzed by different metallic nanoparticles on substrates with lattice mismatch.

A-TEEM Spectroscopy is a unique technology for quality analysis of drinking water, wine and may other agricultural inputs and products. A-TEEM Spectroscopy simultaneously measures the absorbance spectrum and fluorescence (EEM) of Colored Dissolved Organic Matter (CDOM) compounds. A-TEEM Spectroscopy reports NIST-traceable fingerprints which can be evaluated using multivariate statistics such as PARAFAC (Parallel Factor Analysis), PCA (Principal Components Analysis), CLS (Classical least Squares) and PLS (Partial least Squares Analysis). For wine characterization, importantly A-TEEM fingerprints yield qualitative and quantitative composition of key flavor and color determinants in wine and spirits that are not discernible with simple Absorbance or Transmission data analysis. Of the hundreds of different compounds that have been identified in grapes, it is the phenolic content of ripening grape berries that fundamentally determines the quality of a wine.The different classes of phenolics (anthocyanins, tannins, flavonols, catechins) affect the color, the mouthfeel, flavor and aroma to various extent. The individual compounds comprising these classes of phenolics contribute in concert to give the wines their uniquecharacter. The simultaneously acquired Absorbance,Transmission and IFE-corrected EEMdata can be used to evaluate lot-to-lot, regional, and varietal characteristics. For water analysis, Colored Dissolved Organic Matter (CDOM) compounds plays an important role inEPA regulations for drinking water sterilization. The concentration of CDOM compounds inthe humic and fulvic acid classes are regulated because they generate toxic DBPs during halogen disinfection treatments for microorganisms such as Giardia spp. Key parameters of interest includes the absorbance at 254 nm (A254 nm) used in the Specific UV absorbance calculation to predict DBPs and the humic/fulvic/protein like peaks (A/C/T) also correlated with DBPs certified by either NIST and or ISO traceable.

Scalable and green formation of graphitic nanolayers produces highly conductive pyrolyzed paper toward sensitive electrochemical sensors

e-mail: marcos.tinoco@lnnano.cnpem.br

While pyrolyzed paper (PP) is a green and abundant material that can provide functionalized electrodes with wide detection windows for a plethora of targets, it poses long-standing challenges against sensing assays such as poor electrical conductivity, with resistivities generally higher than 200.0 mΩ cm (e.g., gold and silver ~0.2 mΩ cm). In this regard, the fundamental hypothesis that drives this work is whether a scalable, cost-effective, and eco-friendly strategy is capable of reducing the resistivity of PP electrodes toward the development of sensitive electrochemical sensors, whether faradaic or capacitive. We address this hypothesis by simply annealing PP under an isopropanol atmosphere for 1 h, reaching resistivities as low as 7 mΩ cm. The annealing of PP at 800 or 1000 °C under isopropanol vapor leads to the formation of a highly graphitic nanolayer (~15 nm) on the PP surface, boosting conductivity as the delocalization of π electrons stemming from carbon sp2 is favored. The reduction of carbonyl groups and the deposition of dehydrated isopropanol during the annealing process are hypothesized herein as the dominant PP graphitization mechanisms. Electrochemical analyses demonstrated the capability of the annealed PP to increase the charge-transfer kinetics, with the optimum heterogeneous standard rate constant being roughly 3.6×10^{-3}cm s^{-1}. Freestanding fingers of the annealedPP were prototyped using a knife plotter to fabricate impedimetric on-leaf electrodes, ensured the real-time and in situ monitoring of the loss of water content from soy leaves, outperforming non-annealed electrodes in terms of reproducibility and sensitivity. Such an application is of pivotal importance for precision agriculture and development of agricultural inputs. So the new conductive PP in a scalable, low-cost, simple, and eco-friendly way, providing new opportunities to sensitive electrochemical devices.

Study of a ZnO gas sensor produced by slot-die coatingand using atmospheric pressure plasma treatment

Recently, interest in flexible and printed electronic devices has grown due to their application advantages, such as wearable technologies that can be integrated into the Internet of Things (IoTs) [1]. It is interesting to integrate the sensing of gases, arising from volatile organic compounds, as wearable devices, which can be attached to badges, for example. In this context, atmospheric pressure plasma (APP) technologies are of interest asa way of deposition, treatment, or surface modification of flexible materials, as vacuum equipment is not necessary, with low process cost [2]. With this objective, to integrate the use of sensors in flexible devices, the gas sensor based on ZnO operating at room temperature and the study of the modifications created by the APP in the treatment of the substrate and device will be presented [3]. Optical, morphological, and electrical characterizations of the film used in the active layer of the sensor and of the substrate and device treated by plasma were carried out. For the performance of the devices, measurements of sensitivity, response as a function of temperature, and selectivity of alcohol vapors were carried out.

The present describes an electrocatalytic film consisting of a self- assembled monolayer functionalized with ferrocene (Fc). The synthesis was carried out in a gold electrode, from the chemisorption of 2-aminoethanethiol (CIS), followed by o-Phenylenediamine (OPD) binding via the presence of a dicarboxylic acid. The Fc was carried out to the film via OPD through π-π interactions which resulted in a stable functionalization [1]. The electrocatalytic activity of the Fc film was confirmed at the electrode-electrolyte interface by a cyclic voltammetry technique, in the presence of support solution (0.1 M KCl). Electro-oxidation is observed at a redox potential of 0.34 V and 0.15 V for the oxidation and reduction peaks, respectively [2]. As a proof of concept, the electrocatalytic film was mounted over the configuration of a field effect transistor (FET), and it was possible to detect the presence of bovine serum albumin by the change in the drain current measured. The ferrocene-functionalized film stages were all electrochemically characterized by cyclic voltammetry technique. The electrocatalytic film developed shows up as a potential for application in immunosensors, since the electrooxidation potentials do not compromise the activity of biomolecules. In addition, the use of the film has the advantage of dispensing redox probes or the use of marked antibodies in voltametric readings [3].

Synthesis and characterization of Eu-doped ceria nanostructures with controlled morphologies for humidity sensing

Over the last decade, particular interest has been devoted to the morphology-controlled synthesis of various metal oxide semiconductors to investigate the correlation between surface modifications and properties [1]. In this work, Eu-doped CeO2 nanostructures with sphere, rod, cube, and polyhedron morphologies were synthesized via the microwave-assisted hydrothermal (MAH) method. The samples were characterized by multiple structural and optical techniques. XRD analysis showed that ceria's fluorite-type structure was formed for all samples, without secondary phases. Raman spectroscopy analysis showedthat oxygen vacancies were the main defect in the samples. SEM and TEM microscopiesshowed the morphologies evolved from spherical nanoparticles to nanocubes by increasingthe synthesis temperature. These nanostructures were then used to fabricate films by the screen-printing technique. The nanostructures were mixed with organic vehicles to optimizethe deposition process and enhance the adhesion to the substrate. The films were depositedonto alumina substrates with interdigitated gold electrodes and heat-treated to eliminatethe organic compounds. The films were characterized by SEM and had their electrical properties measured under different temperature and relative humidity (RH%) conditions. The films were porous and without cracks or other discontinuities. Increasing the temperature enhanced the response of the films to humidity. The films were able to detect different RH% and the nanorod-based film displayed the best performance for humidity sensing compared with the other samples.

Synthesis and Characterization of Silver Nanoflowers and Silver Nanostars and their Application as SERS substrate for Pesticides Sensors in Aqueous Solutions

Lucas Bragança de Oliveira[1], William da Silva Martini[1], Diogo Silva Pellosi[1], Rômulo Augusto Ando[2]

[1]Federal University of Sao Paulo (*Química*) , [2]University of São Paulo (*Química*)

e-mail: braganca.lucas@unifesp.br

Metallic nanoparticles such as silver nanoparticles (AgNP) have been of great interest in recent years due to their highly interdisciplinary applicability, since they have very characteristic physical and chemical properties such as strong light absorption and, because of their capacity of producing surface plasmon resonance (SPR) effect through excitation of electron oscillation vibrational modes, which yields intensification of Raman spectra (SERS - Surface-enhanced Raman Scattering - effect), makes them great materials for sensing the presence of organic molecules, such as pesticides, in aqueous solutions even though they present very low concentration limits in the order of ng/L [1]. Because of that it is of extreme importance to obtain well synthed substrates capable of supporting these nanoparticles and making possible their application and further detection and identification of pollutants in water resources [2]. Therefore, the present work proposes the engineering of thin films composed of different morphologies (star and flower) silver nanoparticles through the deposition of this materials onto glass substrate using blade coating method to detect the presence of atrazine, thiamethoxam and imidacloprid pesticides in aqueous solutions. UV-VIS spectra, dynamic light scattering (DLS) measurements, atomic force microscopy (AFM), and scanning electron microscopy (SEM) confirmed the morphologies and topography of AgNP films. Due to plasmon effect of AgNP the pollutant models were detected at very low concentrations (10^{-4}~10^{-6}M) in an aqueous solution by SERS effect. These promising results augur well for further developments of AgNP plasmonic thin films for organic pollutants detection.

e-mail: lais.brazaca@usp.br

It is known that the use of nanoparticles in (bio)sensing can significantly improve analytical performance through catalytic properties, or the increase in the number of bioreceptors in the electrode surface, for example. In this work, we have explored the influence of gold nanoparticles (AuNPs) electrodeposition time on the analytical parameters of electrochemical biosensors. For that, AuNPs were added to screen-printed carbon electrodes (SPCEs) using electrodeposition times ranging from 9 to 90s, providing AuNPs with different diameters (143 ± 31 to 752 ± 207). The platforms were modified with anti-S protein antibodies, allowing the label-free detection of S protein from both SARS-CoV and SARS-CoV-2 through electrochemical impedance spectroscopy (EIS). As expected, increased electrodeposition time led to higher concentrations of electroactive species, AuNPs with higher diameter, as well as lower charge transfer resistance. However, the the electrodeposition time was inversely correlated to the enhancement in sensitivity, specificity, and limit of detection. This is probably because thin films present lower capacitive currents, increasing the sensitivity of the devices. The biosensor built with the 9s deposition time was the one that displayed the best performance among the ones tested (9, 30 and 60s), being able to detect S protein in the range from $10^{-11}$to 10^{-7}mol/L and reaching a limit of detection of 3.16 pmol/L. The devices were used for the determination of SARS-CoV-2 inactivated viruses in real saliva samples and were able to differentiate samples from diseased individuals (10^{6}PFU/mL of SARS-CoV-2) from healthy ones. The analysis was completed in 35 min using small sample volumes (10 µL) and is estimated to cost less than US$ 0.03 per device. We expect these studies to aid in the development of future nanomaterials-based biosensors, as a means of increasing its sensitivity, specificity, and other analytical parameters. Acknowledgement Fapesp 2018/19750-3.

Titanium Oxide Nanoparticles: Synthesis andApplication in Isopropyl Alcohol Detection

Renan Barbieri Estefani[1], Angela Alidia Bernal Cárdenas[2], José Pedro Mansueto Serbena[3]

Production of oxide based chemical sensors have been widely studied, although most of them only perform at high temperatures [1]. In this study, an isopropyl alcohol sensor, working at room temperature, based in titanium oxide nanoparticles (TiO_2NPs) is proposed. The TiO_2NPs were synthetized by the Sol-Gel method, where the precursor solution was a mixture of titanium isopropoxide with isopropyl alcohol. After stirring, the precursor solution was slowly mixed with a previously prepared and heated solution of hydrochloric acid diluted in ultrapure deionized water. After cooling, the liquid was centrifuged to separate the resulting in TiO_2NPs that were later dispersed in isopropyl alcohol, as reported in [2]. The material was used as active layer in a chemical sensor for isopropyl alcohol detection by casting the TiO_2NPs dispersion on electroless nickel immersion gold (ENIG) interdigitated electrodes on glass-reinforced epoxy laminate material (FR-4) substrates. The sensor characterization was done through impedance spectroscopy measurements at different analyte concentrations in a sealed static chamber filled with nitrogen at room temperature. The best operating frequency obtained was 3 kHz, chosen considering signal to noise ratios and sensitivities in the range 100 Hz and 20 MHz. The sensitivity at 3 kHz was $5{,}93\text{x}10^{-3}\text{ppm}^{-1}$. These results indicate a possible application of titanium oxide nanoparticles as active material in volatile organic compounds sensors at room temperature.

Contactless luminescent thermometers provide accurate and real-time temperature detection, bringing new technologies to human health diagnoses. For optical temperature detection in vivo, neodymium-doped materials are promising candidates due to their excitation and emission in biological windows, improving penetration depth in the bio-tissue. However, the relative sensitivity depends on the matrix in which the Nd is inserted, excitation wavelength, as well as on the synthesis method. For this work, two yttrium fluoride-based materials doped with 1 mol% of Nd^{3+}were produced using microwave-assisted hydrothermal (MAH) reaction. During nucleation process and posterior thermal treatment, fluoride compounds tend to absorb oxygen ions, changing their structure and, consequently, optical characteristics. Based on these changes, two crystalline matrices were obtained: $YF_3$and $Y_70_6F_9$(inspected via X-ray diffraction - XRD), with rod-like morphology for both compounds, as determined by SEM images. The oxygen content was thoroughly investigated by XPS analyses and correlated to the thermal sensitivity of the two materials. Based on LIR (Luminescence Intensity Ratio) methodology, the highest sensitivity value was achieved for 660 nm excited Nd-doped Y706F9 sample, presenting relative sensitivity of 1.6%K-1. These results indicate that materials are promising contactless temperature sensors for in vivo applications, and its direct connections with synthesis parameters.

Acknowledgments: The authors thank FAPITEC and CAPES for the scholarship grant. CMNano-UFS and LNNano for the facilities.

3D printed electrochemical sensor based on carbonblack for determination of Carbendazim in honey

Electrochemical sensors obtained by additive manufacturing have gained prominence in the scientific community due to the possibility of large-scale production, the use of sustainable/renewable materials, and the relatively low cost [1]. In addition, in recent years, together with additive manufacturing, the production of conductive filaments has gained more and more space, allowing the manufacture of custom-made sensors with the most varied composition [1,2]. Such 3D printed sensors have shown remarkable performance and applicability in the most different areas of society, such as the detection of pesticides in food matrices. In this regard, the present work applied a lab-made conductive filament based on carbon black and polylactic acid to produce an electrochemical device for detecting carbendazim (CBZ) in honey. The manufactured electrochemical sensor was electrochemically treated in a basic medium to remove excess PLA of the surface and expose the conductive material. Thus, the sensor showed a superior response for CBZ detection. Thus, an analytical curve was built in the range from 0.5 to 20.0 μmol L-1 with a limit of detection of 0.1 μmol L-1. Furthermore, recovery tests carried out in honey samples from fortification with three known concentrations showed values close to 100%, demonstrating that there is no significant matrix effect. Therefore, it is possible to infer that the production of electrochemical sensors from lab-made conductive filaments was successfully reached, demonstrating the applicability of the material since it was possible to determine CBZ easily and simply in sub-micromolar concentration.

e-mail: vinicius.silva@estudante.ufscar.br

Electrochemical sensors built by additive manufacturing have been applied in several research areas. Researchers have exploited the ease of modeling, rapid prototyping, and high definition offered by this technique, together with conductive filaments, to produce new sensor architectures.[1] Dual extrusion has grown in this segment, offering the possibility of working with two materials simultaneously, avoiding defects caused during the assembly of a device produced separately. In this work, a device built by dual extrusion additive manufacturing, using thermoplastic and conductive filaments based on carbon nanomaterial, was proposed for the detection of the pesticide fenitrothion in honey samples for monitoring its application in the field and as quality control in food samples.[2] The construction of the device was carried out using a 3D printer with the Fused Deposition Modeling technique, which was subsequently treated with dimethylformamide and washing it in ethyl alcohol and an ultrasonic bath in ultrapure water.[3] The morphological characterization of the sensor was performed before and after the treatment by scanning electron microscopy, which is possible to visualize the removal of Polylactic Acid from the surface and exposure of carbon black. The square wave voltammetry technique was used, in which the sensor reached the highest peak current for fenitrothion detection. Under optimized parameters, the analytical curve was built, comprising a linear concentration range from 4.0 to 200 µmol L^{-1}, and a limit of detection of 1.3 µmol L^{-1}. The proposed sensor is being applied to honey samples, proving to be effective in detecting fenitrothion.

e-mail: naylanaomi@alumni.usp.br

Tuberculosis (TB) cases and deaths have increased in Brazil since last year [1]. Early detection is crucial for the effectiveness of treatment. The standard method for diagnosis, the mycobacterial culture, has a slow growth rate (about 8 weeks), which can worsen the patient's health condition [2]. An alternative for fast and sensitive diagnosis is using biosensors based on nanomaterials due to their unique properties. Hydroxyapatite nanoparticles (HANps) have easy adsorption of molecules on their surface and exhibit photoluminescence (PL) by manipulating defects in their structure [3]. This project aims to develop a fluorescent biosensor for the detection of the CFP10/ESAT6 complex, a TB biomarker. HANps were synthed following the method established by Machado et al [3] and functionalized with polyethyleneimine (PEI). Abs against CFP10/ESAT6 were covalently bonded to HANps-PEI and BSA was used as a blocking agent. Fourier-transform infrared spectroscopy, surface zeta potential, and PL spectroscopy characterized each functionalization step, indicating the successful Abs immobilization onto HANps. Significant changes in the intensity of the PL spectrum step were noticed. The results have shown that the nanosensor is promising to be used as a detection probe for the accurate, fast, and low-cost diagnosis of TB.

Pediatric acute lymphoblastic leukemia (ALL) is a hematopoietic neoplasm responsible for high mortality in children. The current diagnosis is based on a series of investigations, however, for clinical decision-making, genetic markers are decisive. Despite this, these genetic methods need a long time to respond and more than one is needed to confirm the neoplasm. The translocation between chromosomes 4 and 11 (t(4;11)) is a poor prognosis mutation in childhood [1]. Biosensors are tools that provide fast response with easy instrumentation, especially when associated with electrochemical transduction. In addition, materials such as conductive polymers and nanoparticles are introduced in the structuring of biosensors to improve bioanalytical performance [2]. In this context, our objective is the development of a DNA biosensor to detect t(4;11) in pediatric patients with ALL. For this, the electropolymerization of PPy was carried out on a surface of flexible working electrode. As a second step, the quantum dots were adsorbed followed by primer immobilization to t(4;11). Biorecognition assays were performed with plasmid samples. Cyclic voltammetry was used to characterize the steps of construction and evaluation tests. As a result, voltammetric changes were observed for each self-assembly and biorecognition step. With the ΔI% it was possible to observe the hybridization process. Thus, the DNA Biosensor developed proved to be suitable for use in the diagnosis of ALL.

The development of nanotechnologies and new 2D materials has enabled a search for faster, more selective, and portable gas sensors that are capable of meeting the demands of areas such as industrial safety and environmental monitoring. In this context, due to its high electronic mobility and large surface area, graphene-based materials show promise for use as gas sensors [1]. Currently, several strategies are developed to improve the sensing properties of ZnO, one of these techniques is the combination of ZnO with reduced graphene oxide (rGO). Thus, this research aims to prepare sensors from ZnO and its combination with rGO, to evaluate the ability of these samples to detect ozone. ZnO was synthesized by controlled precipitation, using ammonium hydroxide as a precipitating agent and zinc acetate as a precursor [2]. The sensors were manufactured by drop casting ZnO solutions and rGO dispersion on interdigitated platinum electrodes, being named ZnO and ZnO-rGO-ZnO sensors. By XRD, the formation of a compact hexagonal crystalline structure of the ZnO wurtzite type was verified without the presence of impurities. ZnO SEM images showed that needle morphology was produced. Measurements of gas detection at different temperatures demonstrate that both sensors present a higher response at 200 °C and that the ZnO-rGO-ZnO sensor presented an average response 30 times greater than that of the ZnO sensor.

Acknowledgments: This research was funded by Sao Paulo Research Foundation's financial support - FAPESP (grants N° 2022/06404-5, 2019/22076-5, 2022/03325-7, 2023/00913-8, and 2013/07296-2). The authors are also grateful to the Brazilian National Science Financial Agencies CNPq and Capes.

e-mail: idomeneu.filho@ifto.edu.br

Faced with the need to expand food production, due to population growth, and global warming with more irregular rainfall, the relevance of irrigation in agriculture has increased. In this sense, new technologies to increase the efficiency of water use with lower costs are needed. Our project aims to develop an automation system, powered by solar energy, with automatic control function (on and off) of the water flow in an irrigation system for small rural properties. We acquired equipment to set up the automation system with a low-cost arduino microcontroller, model uno, powered by an off-grid solar system [1] and connected to sensors responsible for measuring soil and air humidity, which will be used in the activation autonomous from the irrigation pump. First, we use an inorganic silicon solar panel. Later, we will use an organic solar panel (OPV) based on carbon: lighter, more flexible, semi-transparent and more sustainable than traditional models. The effectiveness of the prototypes developed in our laboratory will be carried out with data collection in a low-income family property in the southern region of Tocantins. Thus, it is expected to offer a viable alternative to reduce operating costs in an automation system.

e-mail: paulo.oliveira@ufscar.br

The COVID-19 pandemic exposes the limitation of access to accurate devices for monitoring viral diseases. Hence, searching for new monitoring devices, focusing on accuracy, simplicity, and low cost, has been exhaustively done [1]. On the other hand, the development of new, more sustainable analytical platforms become another challenge, aiming to avoid environmental problems generated by sensor discarding. This work focuses its efforts on the construction of a biodegradable and waterproof substrate for the manufacture of SPEs, using commercial inks. Here, we focused on the use of beeswax (BW) to make commercial paper waterproofed (WPpaper) for subsequent screen-printing manufacturing. The SPEs were printed in polyester, non-waterproof paper, commercial universal spray protector water-repellent, and beeswax-based waterproof paper substrates, respectively, in which the BW promoted the best waterproofness to the paper. Structural and chemical properties of all substrate and electrode surfaces were characterized by XPSand SEM. Their electrochemical performance is benchmarked against the near-ideal outersphere redox probe hexaamineruthenium (III) chloride. The WP paper exhibited a HET rateconstant 133% higher than the non-WP paper. Regarding the waterproofness, only 40 μg ofBW per electrode increased the water contact angle from 96.8° to 126.6°, considered highlyhydrophobic. Finally, after cyclic voltammetry analysis, the SPEs WPpaper-based presented43.3% less current variation, after 100 cycles, compared to the non-WPpaper, similar to results obtained for the SPEs polyester-based. Therefore, WPpaper could be used as a cheaper and environmentally friendly alternative to commonly used substrates, such as polyester.

The agrobusiness is one of most important economic sectors in Brazilian economy, being also one of the most polluting sectors causing environmental and social impact. Many producers dispose irregularly pesticides and mishandle them, polluting the soil and water bodies(SINGH et al., 2016). Sensors are applied to detect pesticides to point out which substance is being used in that culture and to inspect whether the producer is within the legislation(KILLEDAR et al., 2022). This work studies a sensor based on polyvinyl acetate and carbon lignin (YAO et al., 2022), being biodegradable and dismissing the use of organic solvents to detect Carbendiazin, a wide range fungicide applied in fruit and cereal crops. The carbon lignin was obtained but carbonization of lignin kraft in nitrogen atmosphere, then added to PVA to obtain a conductive film to build the sensor up. The sensor is investigated using scanning electron microscopy (SEM) and energy dispersive X-ray spectroscopy (EDS) and Electrochemical study (cyclic voltammetry and Electrochemical Impedance Spectroscopy). The results are analyzed by analysis of variance (ANOVA) to verify significant detection of Carbendiazin applying the proposed sensor. SEM makes it possible to observe the distribution of lignin though the polymeric matrix, EDS pointed the non-crystalline surface being able to identify the adding of lignin in the polymeric matrix and the electrochemical study presented the efficiency of sensor as a conductive material, and its feature of detecting the fungicide (MACIEL et al., 2022).

Colloidal aqueous synthesis and structural characterization of cobalt doped ZnO nanoparticles

Zinc oxide (ZnO) is an intrinsic binary n-type semiconductor material that belongs to class II-VI, has a direct band gap in the near UV (E_g= 3.37 eV at room temperature), and has an excitonic binding energy of 60 meV. This semiconductor is considered a good host network for doping elements, such as isovalent transition metals (MTs), which have an ionic radius comparable to $Zn^{2+}$and high solubility inside the ZnO matrix [1]. The main strategies established in the literature for obtaining doped ZnO nanoparticles (NPs) are based on co-precipitation or the use of organic solvents. However, colloidal approaches are alternative methodologies to achieve ZnO NPs with lower cost and easy reproducibility [2]. Thus, the present work propose a synthetic method via colloidal chemistry in an aqueous medium to produce cobalt-doped zinc oxide nanoparticles (Co:ZnO NPs). Nitrate salts of zinc and cobalt were used as precursors at a molar fraction according to the expression, $Zn_{1-x}Co_xO$(x= 0.05, 0.075, 0.10), and mercaptosuccinic acid (MSA) as a surface stabilizing agent. The results of X-Ray diffraction (XRD) confirmed the formation of Co:ZnO NPs with an averagediameter variating between 8 - 18 nm. The Transmission electron microscopy (TEM) measurements showed that these Co:ZnO NPs have quasi-spherical morphologies and average sizes of about 9.5 nm. The compositional analyses by energy dispersive X-Ray spectroscopy (EDS) confirmed the doping of ZnO with cobalt. These results suggest thesuccess of the aqueous colloidal route to achieve doped ZnO NPs, which have potentialapplications in several areas of nanotechnology such as sensors, photonics, optoelectronic,photocatalysis, and magnetism.

The localized surface plasmon resonance (LSPR) of gold nanorods (AuNRs) is a label-free biosensing technique known for its sensitivity to changes in the refractive index of the local environment, which is generated by biomolecular interactions around the detection area [1]. LSPR from AuNRs can be used as a sensitive diagnostic tool for important diseases such as PCM. In this study, AuNRs were incubated with different concentrations of the functionalizing agent (2, 4, 6, 8, 10, 12, 14, 16, 18, and 20 mM) and then with different concentrations of the specific protein (2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 25, 27, 30, 50, and 60 μg) to define the optimal conditions for biosensor construction. The UV-Vis spectra of the solutions were obtained for longitudinal band shift analysis (L-LSPR). A significant shift of L-LSPR was observed for all functionalizing agent concentrations tested, with the shift increasing up to the concentration of 8 mM, after which the system reached saturation. Incubating AuNRs functionalized with different protein concentrations did not yield significant differences in L-LSPR shifts up to a concentration of 14 μg. Between 14 μg and30 μg, the shifts were similar, but at concentrations of 50 μg and 60 μg, signs of aggregation were observed. Based on these results, it is recommended to use a concentration of 8 mM of the functionalizing agent and 14 μg of the specific protein for the construction of the proposed biosensor. The biosensor will be tested with fungal samples in the next steps, and sensitivity and specificity analyses will be performed.

The SARS-CoV-2 pandemic revealed the importance of exploring new low-cost materials for point-of-care devices. Given the relevance of the current scenario, the detection and quantification of antibodies can be used to assess the immune response to infection, the disease prevalence, determine a previous infection, as well as help evaluate the immune response to vaccination. Capacitively coupled contactless conductivity detection (C4D) is a promising methodology for these purposes because the reusable electrodes of the C4D sensors are not in contact with the measured fluid; the drawbacks of the polarization effect and electrochemical erosion can be avoided. Moreover, its quick response does not require complex and expensive electronic equipment. In this context, we developed a biosensor for quantifying IgG antibodies to SARS-CoV-2 using the C4D technique and constructed it from a printed circuit board (PCB) as a durable device. The production process used a PCB with a thin 30 μm thick copper layer and a 35 μm PDMS (polydimethylsiloxane) film as an insulating coating, doped with titanium dioxide to explore the variation of the dielectric constant of insulators in the signal gain of a C4D detector. The channels for sample retention were produced using transparent acrylic. Preliminary analyses using sodium chloride (NaCl) demonstrated that the device exhibited good reproducibility (CV ≤ 3.93%, n = 3) and repeatability (CV ≤ 0.40%, n = 10) and a detection limit of 0.34 mmol L-1. An analytical curve was constructed with six antibody concentration levels ranging from 0.05 to 3.30 μg mL-1 (n = 3). The proposed device demonstrated adequate analytical performance, showing a linear relationship between conductivity measurements and antibody concentration.

Copper oxide films as resistive gas sensors

Ricardo Henriquez[1], Valeria del Campo[2], Claudio A. González-Fuentes[3], Patricio Häberle[4], Rodrigo Segura[5], Leonardo Vergara[6]

[1]Universidad Técnica Federico Santa María (*Physics*) , [2]Universidad Técnica Federico SantaMaría (*Physics Department*) , [3]Universidad de Santiago de Chile (*Fisica*) , [4]Universidad Técnica Federico Santa María (*Physics Deparment*) , [5]Universidad de Valparaíso (*Química*) , [6]Universidad Técnica Federico Santa María (*Fisica*)

e-mail: ricardo.henriquez@usm.cl

Copper thin films 20 nm thick were evaporated on mica, and oxidized by three hours at different temperatures (RT, 100, 200 and 300ºC) and room conditions. Raman spectroscopy and UV-Vis spectrometry were performed in all samples. The characteristic Raman shift peaks corresponding to Cu_2O appear clearly in samples oxidized at RT and 100 ºC; slightly,in those oxidized at 200 ºC; and they disappear in films oxidized at 300 ºC. On the otherhand, the peak corresponding to CuO appears in the films oxidized at 300 ºC and 200ºC(slight); and it disappears in samples oxidized at RT and 100 ºC. The UV-Vis spectra show anabsorption peak in 310 nm, for all samples. Alos, the bandgap was determined: values decrease from 1.97 to 1.78 eV as the oxidation temperature increases, similar to others reported for CuO nanostructured samples[1]. The temperature dependence of the resistancewas determined (between 300 and 390 K). The resistance behavior shows a change in theelectrical transport mechanism depending on the oxidation temperature: the temperaturedependence changes from a metallic type in samples oxidized at RT and 100ºC , to a semiconductor type in samples oxidized at 200 and 300ºC. The analysis based on these three characterization techniques show that for oxidation temperatures of 100ºC and RT, the samples are mainly composed by a Cu_2O layer on the Cu film, whereas for 200 and 300ºC, the CuO is the main constituent of the film. Finally, the performance of the samplesas a gas sensor was tested, measuring the electrical resistance of the films in presence ofethanol gas at low pressure (from $10^{-3}$to 10^{3}Pa). The sample oxidized at 300ºC, present a resistance decrease between $10^{-2}$and 10^{0}Pa of up to 40%; while a slight increase appears between $10^{1}$and 10^{3}Pa, the most sensitivity to the presence of the gas.

Pesticides are chemicals used to kill larvae, ticks, fungi and weeds, claiming to control the diseases caused by these organisms and regulate the growth of vegetation. The main objective of this project is the development of active membranes based on biopolymer functionalized with xantidrol and ninhydrin to selective detection and removal of the carbaryl and glyphosate pesticides. Characterized by techniques such as BET, FTIR, SEM and TG, Chitosan films were prepared in different percentages of 0.75%, 1% and 1.5% (m/m) in acetic acid. To observe the influence of acid on the physical characteristics of the film, tests were performed altering its concentration of 1% and 2% in the synthesis of the films all contend 0.5% of the glycol polyethylene. For functionalization, 9-xantidrol and ninhydrin of 1%, 2% and 3% (m/m) were used where these compounds were added by direct addition to chitosan gel. To observe the interaction between 9-xantidrol, and ninhydrin and chitosan, UV-vis spectroscopy analysis was performed. Through FTIR and TG, it was observed that the samples of the films functionalized by direct addition there was greater evidence in the spectra obtained and greater resistance to thermal degradation, in which the films of chitosan and xantidrol and ninhydrin, both 2%, are better suited to the proposal. Through UV-vis spectroscopy analysis it was possible to construct calibration curves using composite membrane, showing linear curve with R2=0.996 and R2=0.945 for glyphosate and carbaryl, respectively. The applied methodology proved effective determination of glyphosate and carbaryl and can will be used to verify the removal of the pesticides in water samples.

Detection of “date rape” benzodiazepines in beverages with a silver nanoparticle-enhanced microfluid e- tongue

Maria Helena Gonçalves[1], Maria Luisa Braunger, Antonio Riul Júnior[1], Varlei Rodrigues[2]

[1]Universidade Estadual de Campinas (*Física Aplicada*) , [2]Universidade Estadual de Campinas (*Departamento de Física Aplicada*)

e-mail: mariahelenags10@gmail.com

The consumption of benzodiazepines (BNZD) has risen significantly during the COVID-19 pandemic, particularly in Brazil, where easy access to these drugs, making them a popular choice for criminal activities such as drug-facilitated sexual assault, also known as date rape. In this study, we present an electronic tongue (e-tongue) device integrated with microfluidics and nanostructured materials to detect three types of benzodiazepines (flunitrazepam, diazepam, and clonazepam) in various beverages, including alcoholic ones. The device is based on the layer-by-layer (LbL) assembly of poly(allylamine hydrochloride) (PAH) and poly(styrene sulfonate) (PSS) and employs silver nanoparticles synthesized through a chemical process to improve the electrical properties of the LbL films. Impedance spectroscopy and Principal Component Analysis (PCA) were used to analyze the results and identify the presence of benzodiazepines in the samples. The e-tongue successfully differentiated between samples with and without the drugs, demonstrating its potential for drug detection. The proposed method could contribute to public health by providing a rapid and reliable tool for monitoring the illegal use of benzodiazepines in beverages.

Detection of ascorbic acid using a 3D printedcolorimetric sensor

Secondary metabolites are organic compounds produced by plants in response to stress or as a defense mechanism. Although these compounds are not necessary for the plant''s growth or development, they are crucial for its survival [1], as it is the case of ascorbic acid (AA). In this study, we developed a 3D printed colorimetric sensor for detecting AA in liquid samples. The sensor was designed with a hollow microneedle layer and a reservoir layer coated with a composite film of zein and 2,6-Dichloroindondo dye. Upon exposure to AA, the sensor experienced a color change that was quantified using a smartphone to read the RGB patterns of the platform before and after exposure to the analyte. Our preliminary results showed that the platform modified with the 2,6-Dichloroindophenol dye presented a high sensitivity of 47% for AA concentrations ranging from 0.01 to 3 mg mL^{-1}. Furthermore, the platform showed minimal interference with other secondary metabolites, including caffeine, fructose, and H_2O_2, with a maximum sensitivity interference of 12.30%. Our study demonstrates the potential of designing low-cost 3D printed platforms for detecting AA, with applications in various fields, such as in plant and food analysis.

The World Health Organization has established a safe limit of 2.0 mg.$L^{-1}$for iron in drinking water. Atomic Absorption Inductively Coupled Plasma Optical Emission Spectrometry (AAS) is a widely used method for detecting and quantifying metal ions, but it can be expensive and inaccessible. Metal-Organic Frameworks (MOFs) and Calixarenes have both shown potential in detecting metal ions, including iron, in water. A novel photoluminescent sensor has been developed using a post-synthetic strategy to modify the UiO-66-NH_2MOF with calix[4]arene tetracarboxylic acid (CALIX@UiO-66-NH_2). The molecular structure of the calix[4]arene was confirmed using ^1H and ^{13}C Nuclear Magnetic Resonance Spectroscopy (NMR) analysis, and Powder X-ray diffraction (PXRD) was used to identify the crystalline structure of the MOF. The chemical bonding between these two components was confirmed by Fourier-transform infrared micro spectroscopy (μ-FTIR). The CALIX@UiO-66-NH_2presented increased fluorescent emission intensity compared to the MOF and the calix[4]arene and higher sensitivity to Fe^{3+}ions. The detection limit in aqueous media was determined to be as low as 1.6 mg L^{-1}. This study developed a new fluorescent probe, CALIX@UiO-66-NH_2, with enhanced fluorescence emission intensity and greater sensitivity towards Fe^{3+}ions, making it an ideal candidate for sensing applications.

e-mail: gabrielle@estudante.ufscar.br

17α-ethinylestradiol is a synthetic hormone, found in female contraceptives, with pharmacological and chemical characteristics similar to estrogens. Among the related problems, the increased possibility of developing vascular diseases stands out, being directly linked to the contamination of effluents, causing problems to the local ecosystem [1]. The development of disposable sensors shows advantages over other systems, showing versatility in combinations, practicality in manufacturing, mass production and relatively low cost, becoming increasingly compatible in analytical applications [2]. Carbon black was chosen because of its conductive character, its nearly spherical particle structure, which aggregate to form a graphite-like structure [3]. The proposed electrochemical sensor was made with conductive ink based on carbon black and glass varnish applied to detect 17α-ethinylestradiol. A compositional study was carried out for a better proportion between the components of the ink, and its electrochemical (cyclic voltammetry) and morphological (scanning electron microscopy - SEM and Fourier transformed infrared spectroscopy - FTIR) behavior. The sensor was subjected to the choice of the best pulse technique (square wave voltammetry), studies of its parameters (amplitude, frequency and step), in addition to studies for choosing the pH. In the construction of the analytical curve, it revealed a linear range from 0.5 umol to 10 umol of 17α-ethinylestradiol and limit of detection (LOD) of 0,2 umol. In this study, the sensor was subjected to water samples from different cities, obtaining recoveries between 85% and 107.6%.

Disposable electrochemical sensors are alternatives in terms of sustainability and low-cost production when compared with some equipment to make quantitative analyses in environmental, medical, and industrially interesting samples. Paper-based analytical devices (PAD) have great advantages and have been considered sustainable for the characteristics of biodegradability [1]. Because of the relatively lower cost, these enable greater accessibility and easier detection of many compounds that require frequent monitoring. An example is catechol (CA) which is on the list of priority pollutants and needs for monitoring in aquatic environments by international organizations [2]. In this regard, a sustainable and low-cost electrochemical sensor was developed, using paper and a conductive ink with graphite powder and glass varnish, as well as its application for the detection of CA. The device was characterized by the techniques of scanning electron microscopy, X-ray diffraction, cyclic voltammetry and electrochemical impedance spectroscopy. Under optimized parameters the proposed sensor was applied for CA detection, which a calibration curve was obtained for the linear range of 1.0 × 10・6 to 1.0 × 10・4 ・mol L・1, in phosphate buffer pH 8.0, with an R2 of 0.99915. The developed sensor is easy to prepare and the results suggest the viability for the detection of CA in real samples.Acknowledgments:Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP), grants# 2019/23342-0, 2017/21097-3, CAPES (001 and CAPES 09/2020 Epidemias 88887.504861/2020-00) , CNPq,(301796/2022-0). Development of a biosensor for rapid detection of Salmonella in food

Gabrielle Batista Landim Silva[1], LUIS ALBERTO CONTRERAS ALVAREZ[2], Marco Cesar Cunegundes Guimarães[1], Jairo P Oliveira[1]

[1]UNIVERSIDADE FEDERAL DO ESPÍRITO SANTO, [2]UNIVERSIDADE FEDERAL DO ESPÍRITO SANTO (*Departamento de Morfologia*)

e-mail: gabriellelandim@gmail.com

The development of rapid detection techniques for pathogens in foods is still a challenge. Salmonellosis is a foodborne disease and is one of the leading causes of foodborne infections worldwide. In this study, we developed a lateral flow biosensor for rapid detection of Salmonella in food samples [1]. The detection system is based on an immunochromatographic test with gold nanoparticles and antibodies for antigen recognition [2], with results obtained in just 15 minutes after inserting the strip in the sample. The manufactured biosensor has good selectivity and specificity, high sensitivity, with a detection limit of 10^3 CFU/ml, a value below existing commercial tests. The biosensor also showed good repeatability, in addition to being robust, fast and reliable, and could be a favorable alternative for Salmonella screening in foods to ensure food safety.

Development of a Lab-made screen-printed systemtreated with CO_2 Laser Pyrolysis for propranolol detection

Sabrina Cleto[1], Jéssica Rocha Camargo[2], Bruno Campos Janegitz[3] [1]Universidade Federal de São Carlos - Campus Araras, [2]Universidade Federal de São Carlos - Campus Sorocaba, [3]Universidade Federal de São Carlos - Campus Araras (*DCNME*)

e-mail: sabrina.cleto@estudante.ufscar.br

Screen printing is a simple method for producing low-cost and feasible electrochemical systems, requiring only an inert substrate, conductive ink, and a screen/stencil with the desired design. The use of CO2 lasers in the fabrication of sensors is an area of research that has generated much excitement due to its potential to change the efficiency of screen-printed systems [1]. In this regard, a new electrochemical device based on conductive ink made of shellac and graphite [2] was developed using acetate sheet as a substrate, which with four electrodes has been carried out, one of which is the reference, the counter and two working electrodes. Morphological and electrochemical characterizations were performed to arrive at optimal parameters, including laser pyrolysis parameters such as laser distance, potential, and burning speed. The optimized system was applied to propranolol, an important drug for cardiac treatments, as well as for the control of hypertension [3]. The results showed that the modified electrodes exhibited increased sensitivity for propranolol, making it a promising tool for the detection of this compound. This lab-made system has the potential to be a cost-effective and efficient method for the detection of propranolol that can be used in various fields, including pharmaceuticals and environmental monitoring. Development of an immunosensor based in silica optical fiber to determine ciprofloxacin in wastewater

Rafaela Silva Lamarca[1], Douglas Faza Franco[1], Marcelo Nalin[1], Paulo Clairmont F. de Lima Gomes[1], Younes Messaddeq[2]

[1]Universidade Estadual Paulista / Instituto de Química (*Departamento de Química Analítica, Físico-Química e Inorgânica*), [2]Université Laval

e-mail: rafaela.lamarca@unesp.br

Anthropic growth cause the increase of wastewater volume which could impacts environmental matrices such as rivers and lakes [1]. In these wastewaters, so-called pharmaceutical and personal care products are being detected, ranging from hypertensive agents, special care products, stimulants, and antibiotics. Antibiotics, especially ciprofloxacin (CIP), have been widely found in wastewater [2]. In this study, an effective, sensitive, low-cost, and environmentally friendly immunosensor based on optical fibers was developed for CIP analysis in wastewater. A silica fiber of 200 μm diameter, without core, coated with low refractive index polymer was used. A U probe with 30 cm piece was selected and removed 10.00 mm of the coating polymer. The anti-ciprofloxacin antibody was functionalized in the silica fiber and applied in local wastewater samples. The monitored of the optical signal occurred through an evanescent absorbance wave using optical fiber spectrometer. This immunosensor presented a linear range of 0.010 to 1.0×10^4 ng L^{-1}, the detection limit of 3.3×10^{-3} ng L^{-1}, and a quantification limit of 0.010 ng L^{-1} [3]. To validate the developed immunosensor, the data obtained were compared to previous method obtained by Electrochemical Impedance Spectroscopy. At 95 % of confidence through a test-t no significant differences were verified. Both methods presented the same CIP concentration 5.5 ± 0.050 ng L^{-1}.

e-mail: wlira@usp.br

Accurate monitoring of drug concentrations, such as paracetamol, is crucial for optimizing clinical outcomes and managing patients'' medication regimens. Electrochemical sensors offer a cost-effective, flexible, disposable, and efficient tool for detecting biomarkers and monitoring drugs [1,2]. However, gold electrodes are relatively expensive, and other alternatives can be chosen for similar purposes. In this study, we describe a method for producing screen-printed gold electrodes on Polyethylene terephthalate (PET) substrates using thermal evaporation. The electrodes were modified with magnetic nanoflowers/poly(3,4-ethylenedioxythiophene) (PEDOT:PSS) for the detection of paracetamol by using electrochemical methods of analysis. The morphology of the nanoflowers was studied using scanning electron microscopy (SEM). The electrochemical sensor performance was evaluated using cyclic voltammetry (CV) and square wave voltammetry (SWV) in the presence of 0.1 mol L-1 phosphate buffer (pH 6.8). The sensor exhibited a linear response for paracetamol concentrations ranging from 2.5 × 10−8 to 5 ×10−2 mol L-1, with a detection limit of 2.2 × 10−7 mol L-1. These results demonstrate thepotential of this simple strategy for developing stable, reproducible, and sensitive electrochemical sensors that could have future applications in virus detection and cancerdiagnosis.

Difference in fluorescence quenching by GO of anionicand cationic dyes

Danilo Roberto Carvalho Ferreira[1], Estefânia Mara do N. Martins[2], Clascidia Aparecida Furtado[2]

[1]Centro de Desenvolvimento da Tecnologia Nuclear, [2]Centro de Desenvolvimento da Tecnologia Nuclear (*Nanomateriais*)

e-mail: danilorcferreira@gmail.com

A notable property of graphene oxide (GO) is its fluorescence quenching capacity, occurring in two different types: Dynamic (momentary collision interaction) and static (not-fluorescent complex formation). Each of these processes can be described by linear plot using the Stern-Volmer equation. Besides, it is common to observe systems in which both types are present, generating a quadratic Stern-Volmer curve. However, it is required to favor only one type of quenching for some applications, like dynamic quenching for FRET biosensors. For that, to optimize some parameters and characteristics of the medium, fluorophores and quenchers is important to enhance the occurrence of dynamic quenching. In this study, the kinetics of GO fluorescence quenching of four fluorophores with distinct liquid charges are evaluated. For that, the medium parameters like viscosity, temperature and pH have been fixed. Thus, it was observed that process of fluorescence quenching of anionic fluorophores has lower values of association constant (Ka) and positive values for Gibbs free energy (ΔG). Furthermore, in this group the liquid charge is the same of GO in this pH, indicating the repulsive influence of negative charge of both disfavoring the static quenching process. The same conclusion can be taken by observing the relatively high Ka value (2,86) in the interaction of methylene blue (positively charged) and GO. That interaction has a negative ΔG (-2,6 kJ), indicating the favoring of the non-fluorescent complex formation between GO and MB, proving the occurrence of static-quenching process. Therefore, the results show that the distinct electrostatic nature between fluorophore and quencher can be explored to favor one type of quenching and helping to select the optimum dye to construct a FRET biosensor.

Effects of heat treatment on magnetoelastic sensors for application in biosensors

Luiza Felippi de Lima[1], Roberta Dutra[2], Bruno Gomes Silva[2], Rubem Luis Sommer[2], Cesar Aguzzoli[1], Mariana Roesch Ely[1], Cláudio Perottoni[1]

e-mail: luizafelippi@gmail.com

Magnetoelastic sensors respond to mass variations and, due to the possibility of wireless monitoring, are an excellent alternative for application in biosensors. However, for this to be possible, it is necessary to functionalize the sensor surface to promote the detection of the desired pathogen. However, prior to the functionalization step, it is necessary to cover the sensor surface with layers of chromium (Cr) and gold (Au) to promote corrosion resistance and biocompatibility. Heat treatments (HT) are applied to these sensors to provide better adhesion between the deposited metallic layers and homogenization of the magnetic properties, relieving residual stresses from the alloy manufacturing process and the cutting step to obtain the sensors in the required dimensions. In this context, the objective of this work was to evaluate the effect of HT on magnetoelastic sensors concerning resonance frequency, signal amplitude, and corrosion resistance. For this, sensors produced with Metglas 2826MB alloy were covered with layers of Cr and Au via magnetron sputtering, and four groups of sensors were evaluated: (I) without HT, (II) HT before, (III) HT after, and (IV) HT before and after coating. The HT was carried out at 230°C for 2 hours under a vacuum. The resonance frequency and signal amplitude readings were performed with a network analyzer and an electromagnetic coil system. Corrosion resistance was evaluated by optical microscopy analysis after leaving the sensors in ultrapure water for 48h. It was observed that the heat treatment procedure before and after the deposition of the Cr and Au layers reduced the variance of resonance frequency and signal amplitude. Furthermore, this HT procedure also improved adhesion between the Cr and Au layers with the magnetoelastic substrate, thus exhibiting less corrosion evidence than the other groups.

Electrochemical behavior of dopamine on the surface of electrodes modified with manganese ferrite nanoparticles

Recently, metal oxide nanoparticles (NPs) have contributed to the development of more sensitive and efficient electrochemical sensors with better selectivity [1]. Electrodes modified with manganese ferrite ($MnFe_2O_4$) will present improved properties promoted by increased electroactive area and high transfer kinetics [2]. In this context, $MnFe_2O_4$NPs were obtained with different properties, and they were applied to prepare carbon paste electrodes (CPE), which were used to dopamine (DA) evaluation. The NPs were obtained by coprecipitation and hydrothermal methods, using $MnSO_4$and $FeCl_3$(1:2) as precursors at 140°C for 24h, NPs were also prepared under similar conditions using β-cyclodextrin as stabilizing agent, this sample was named as CD-$MnFe_2O_4$. The samples showed magnetic behavior, XRD analysis indicated the presence of monophasic manganese ferrite with a crystallite size of 20 nm for $MnFe_2O_4$and 5nm for CD-$MnFe_2O_4$. The NPs possessed high BET area values of 170 $m^2g^{-1}$and 240 $m^2g^{-1}$for $MnFe_2O_4$and CD-$MnFe_2O_4$respectively, the molhability of the NPs surfaces was measured using the contact angle technique, being 110º for $MnFe_2O_4$and 53° for CD-$MnFe_2O_4$characterizing hydrophobic and hydrophilic surfaces respectively. Differential pulse voltammetry measurements of the modified CPE in the presence of DA indicated that the oxidation potential was 0.16V for CPE-$MnFe_2O_4$and was -0.16V for CPE-CD-$MnFe_2O_4$. Analysis of interferents showed that CPE CD-$MnFe_2O_4$is more selective for DA, because no interference from analytes such as ascorbic acid and uric acid, was observed, meanwhile, for the CPE-$MnFe_2O_4$these analytes interfered in the dopamine response. The electrodes showed a good linear range, low detection limit for DA and good sensitivities.

Evaluation of a dynamic method for sensing dissolved oxygen in blood through Fluorescence Lifetime Imaging Microscopy

Diéricon Sousa Cordeiro[1], Tatiana Duque Martins Ertner de Almeida[1]

[1]Universidade Federal de Goiás (*IQ*)

e-mail: diericonquimicaufg@gmail.com

The accurate measurement of dissolved oxygen in blood plays a crucial role in monitoring various medical conditions and assessing respiratory function. In this context, a sensor based on coumarin and peptide structures has been explored in this study due to their fluorescent properties and oxygen-responsive capabilities[1]. This sensor operates by monitoring the variation in the photophysical behavior of the sensing system in the presence of dissolved oxygen in blood, using fluorescence lifetimes and their dynamic alterations as parameters, caused by specific interactions with molecular oxygen[2]. The interaction of the analyte with the system causes a change in the dynamic response that is correlated to minimal variations in oxygen concentration, allowing detection of nanomolar levels of O_2in the blood. The response is recorded by a Fluorescence Lifetime Imaging Microscopy (FLIM) microscope, which is available and enables local mapping of the analyte''s concentration variations of interest. This sensor can be applied in areas such as patient monitoring during surgeries, evaluation of respiratory therapy efficacy, and studies of pulmonary physiology. Furthermore, the use of coumarin and peptide structures offers the advantage of being biocompatible, allowing for direct application in the biological environment without adverse effects.

Glucose sensors are extensively studied and represent a feasible route for introducing innovative sensor designs. This work presents two simple architectures for hybrid organic/inorganic biosensors, with titanium dioxide (TiO2)/indium tin oxide (ITO) thin films as electrodes and glucose oxidase as the catalyser. In the first, compact TiO2 films were fabricated by sputtering and a sol-gel methodology, combined with spin-coating, using titanium ethoxide as the precursor. For the second structure, a self-assembly methodology using pluronic® F-127 as a mesoporous template, together with titanium ethoxide, was used. Self-assembled mesoporous films presented the best cohesion with the substrate/ITO, low microscale crack density as observed by scanning electron microscopy and higher in-plane electrical conductivity. Furthermore, as attested by Raman spectroscopy, the anatase phase has been observed on TiO2 films after synthesis and calcination between 400 and 520°C. Therefore, mesoporous TiO2 thin films present the best biosensor application characteristics due to larger surfaces than compact films. Preliminary results showed, after sensibilization, that all the TiO2 films exhibited an evident change in resistivity in the presence of glucose. Finally, a consistent methodology for fabricating a transducer with a simple and reproducible design is proposed.

Fe_2O_3-based microbial volatile organic compoundssensor

e-mail: bruna.sa@unesp.br

Microbial volatile organic compounds (MVOCs) are compounds with high vapor pressures and low molecular mass produced by bacteria and fungi [1]. These microorganisms and, consequently, their metabolites can be problematic factors in indoor environments, as they are related to general symptoms of respiratory-tract and eye irritation [2]. Therefore, the development of sensor materials for MVOCs detection is imperative. Sensors based on semiconductor metal oxides (SMOx) are very reported in the literature due to their high performance in detecting gases. Likewise, in the present work, it was produced and characterized the SMOx Fe_2O_3. First, a precursor was synthed, in a Schott bottle, by the mixture of ferric chloride, 1,4-benzenedicarboxylic acid, N,N′-dimethylformamide, and polyvinylpyrrolidone. The mixture was vigorously stirred for 1.5 h at 145 °C. Then, the precipitate was centrifuged and washed with ethanol anhydrous twice [3]. Finally, the precursor was calcined to produce Fe_3O_2. The samples were characterized by X-ray diffraction and field-emission scanning electron microscopy. The sensor test was performed for ethanol, 3-methyl-1-butanol, acetone, 2-butanone, and isovaleric acid at different operating temperatures (200-450 °C). The sensor showed greater selectivity for 3-methyl-1-butanol at 350 °C.

The nitrogen-vacancy (NV) center is a defect in which two adjacent sites in diamond’s tetrahedral lattice of carbon atoms are replaced. One site contains a nitrogen atom instead of carbon while the other is vacant. In its negatively charged state, the NV center gains an extra electron from the lattice, forming a ground state spin system which can be polarized with 532-nm light, even at room temperature. One of the spin states fluoresces much more brightly than the others so that fluorescence can be used for spin-state readout. At the same time, the NV’s electron spin states are sensitive to magnetic and electric fields. These properties make NVs attractive both as a scalable platform for quantum information systems and for high sensitivity electromagnetic field quantum sensors. An integrated optics platform in diamond is essential for both quantum information systems and quantum sensing, where the NV is used as an optically detecting atomic probe. This is because of the ultimate stability and integration provided by monolithic waveguides, in addition to the potential for enhanced optical interaction with NVs. We present results on the femtosecond laser microfabrication of optical waveguides, microfluidics, graphitic pathways and quantum emitters, crucial building blocks for quantum sensing within diamond. We use a microfluidic pump, scanning electron microscopy, confocal fluorescence microscopy, optical waveguide transmission and second order intensity autocorrelation to characterize the performance of these quantum sensing building blocks. In addition, a hybrid fabrication method is introduced whereby ion implantation is used to form NV quantum emitters at nanometric depths at the end facets of laser written optical waveguides. This hybrid fabrication scheme enables development of 2D quantum sensing arrays, facilitating spatially and temporally correlated magnetometry.

e-mail: leony.oliveira@ufpe.br

Cervical cancer is associated with high mortality in women diagnosed with high-risk HPV (human papillomavirus) types. The E6 and E7 genes are used as important oncomarkers. However, current genetic diagnostic methods demonstrate limitations of rapid response with complex protocols. Genosensors are attractive tools that have fast real-time detection [1]. Furthermore, flexible substrates are applied in the structuring of devices, as they provide significant electrochemical and physical properties. In addition, polypyrrole (PPy) and gold nanoparticles (AuNs) provides an increase in the electroanalytical signal [2]. Thus, the objective of this work is the development of a flexible genosensor based on PPy and AuNs for the detection of oncomarkers E6 and E7. For this, a modified flexible ITO was used with the following construction steps: PPy electropolymerization, AuNs electrosynthesis, Cys dripping and primer immobilization. All construction steps and biorecognition tests were characterized by cyclic voltammetry and electrochemical impedance spectroscopy. For biorecognition tests, cervical scraping suspensions were used. Electrochemical changes were observed according to the self-assembly of the genosensor. In the biorecognition tests, there was an increase of ΔI% related to the sample concentration. This indicates the hybridization process. Thus, the developed genosensor can be considered an innovative toolapplied in the oncogenic screening of HPV.

Although semiconducting metal oxide (SMOx) nanoparticles (NPs) have drawn attention as sensing materials, the methodologies available to synthesize them with desirable properties are quite limited and/or often require relatively high energy consumption.[1,2] Thus, we report herein the processing of Zn-doped SnO_2NPs via a microwave-assisted nonaqueous route, at a relatively low temperature (160 °C) and with a short treatment time (20 min). In addition, the effects of adding Zn on the structural, electronic, and gas-sensing properties of SnO_2nanocrystals are investigated. XRD and HRTEM analyses revealed the single-phase of SnO_2, with particle size of 7 nm. XANES measurements revealed the homogenous incorporation of Zn ions into the SnO_2network. From the sensing viewpoint, the results showed that Zn-doped SnO_2NPs were highly sensitive to sub-ppm NO_2levels at 150 °C, presenting good recovery and stability. Also, the Zn-doped SnO_2NPs revealed good stability of their NO_2sensing performance even under ambient moisture. The enhancement in the gas-sensing properties was linked to the Zn ions incorporated that provided more surface oxygen vacancies acting as active sites for the NO_2adsorption on the sensing material.

Gas sensor performance of porous ZnO flowers synthesized by microwave-assisted hydrothermalmethod

Amanda Akemy Komorizono[1], Valmor Roberto Mastelaro[1]

[1]Instituto de Física de São Carlos - USP

e-mail: amanda.akemy@hotmail.com

The detection and monitoring of toxic and flammable gases have grown considerably in the last two decades due to increased industrialization. As a result, low-cost, high-sensitivity, and low-energy gas sensors are increasingly in demand. ZnO gas sensors have attracted a lot of attention due to their high chemical stability, non-toxicity, high sensitivity, low cost, and easy fabrication [1,2]. Therefore, the objective of this work is the development of porous ZnO flower sensors for the detection of toxic gases. ZnO was synthesized by microwave-assisted hydrothermal method using zinc nitrate hexahydrate as a precursor. The synthesized powder was thermally treated at 700 °C to create porosity in the material. ByXRD it was identified that the synthesized material is ZnO with a wurtzite structure. SEMimages show that the morphology obtained was porous flowers. Detection measurements forgases demonstrate that the sensor has a high response for $O_3$when compared to $NO_2$and CO, thus indicating that the sensor is more selective for O_3 gas.

Acknowledgments: This research was funded by Sao Paulo Research Foundation's financial support - FAPESP (grants No 2019/22076-5, 2022/03325-7, 2023/00913-8 and 2013/07296-2). The authors are also thankful to the Brazilian National Science Financial Agencies CNPq and Capes.

Glyphosate Analysis In Water Samples By Luminescence Spectroscopy Using Lanthanides AsChromophores

Raquel A. Domingues[1], Talita Nunes de Faria[2], Maraísa Gonçalves[2], Denis Augusto Turchetti[3]

[1]Federal University of Sao Paulo (*ICT*) , [2]Federal University of Sao Paulo, [3]Universidade Federal do Paraná

e-mail: radomingues@unifesp.br

Glyphosate is an active ingredient from herbicides that controls weed and grass development [1]. Its non-selective characteristic harms unwanted plants both in agricultural and nonagricultural zones. When glyphosate is already in the soil, its natural degradation occurs under aerobic and anaerobic conditions by soil microflora [2]. Studies in rodents related to acute exposure to glyphosate and its formulations have shown that the growth was delayed in high-dose females with long-term glyphosate exposure. For high-dose in males, there was a significant increase in the degenerative lens and a liver increase [1]. Consequently, incorrect management that leads to considerable residual spread in the environment, such as in aqueous media, could be dangerous. Based on this, the development of techniques seeking glyphosate analysis by analytical methods has been broadly studied for the past years. However, many methods still require expensive resources, making them impractical. Thus, the present work embraced quantitative glyphosate analysis in water samples by luminescence and UV-Vis absorption spectroscopy, using lanthanides complexes as chromophores, $Eu(DPA)_3$and $Tb(DPA)_3$. With the developed method, glyphosate concentrations could be analyzed based on Brazilian regulations. The developed method had its result compared to a well-established HPLC methodology. Glyphosate complexation has shown photophysical changes after the interaction between glyphosate and metals. One of the main points of this work was the possibility of identifying low concentrations of glyphosate to verify water potability; those concentrations were around 10^{-6}mol. L^{-1}, or 0.5mg. L^{-1}, values recommended by WHO (World Health Organization).

e-mail: lucasbarros521@gmail.com

Graphene oxide quantum dots (GOQDs) are semiconductor nanocrystals that possess optoelectronic properties which can be controlled by size, molecular structure, and the surrounding physicochemical environment. The fluorescent emission of GOQDs can be quenched upon interaction with metallic ions, making them useful as fluorescent probes in chemical sensors. In this study, we developed an aqueous GOQD suspension for detecting Cu2+ ions. The GOQDs were synthesized by reducing the size of graphene oxide sheets with ammonia and hydrogen peroxide [2], and their structural features were fully characterized using FT-IR and Raman spectroscopy. They absorb at 220 nm and emit at 537 nm, with emission intensity increasing with pH in the range of 4 to 10. At pH 5, the intensity of the fluorescent emission scales linearly (R2 >0.99), but inversely with the concentration of Cu2+ in the range of 1 to 100 micromolar, with a limit of detection of 2.2 micromolar (S/N = 3). It is hypothesized that Cu2+ ions coordinate with carboxylic acid groups in the GOQDs, which are responsible for the fluorescent emission.Acknowledgments: FAP-DF, CAPES, and CNPq.References:[1] P. Graphen Quantum Dots and Carbon Black nanocomposite for sensitive electrochemical determination of 17-α-ethynilestradiol

Mayara da Silva Araujo[1], César Ricardo Teixeira Tarley[2], Roberta Antigo Medeiros[1]

[1]Universidade Estadual de Londrina (*Química*) , [2]Universidade Estadual de Londrina

e-mail: asmayara@uel.br

Graphene quantum dots (GQDs) and carbon black (CB) are nanoparticles with electric properties interesting for application in different electrochemical devices, as electrochemical sensors [1]. The present work describe the synthesis and characterization of GQDs nanoparticles and their combination with CB, to modify the glassy carbon electrode and develop a electrochemical sensor (GQDs-CB/GCE) for 17-α-ethynilestradiol (EE2) determination. To synthesis of GQDs, 1,0 g of CA was heated, in vegetal oil bath, at 200ºCfor 30 minutes, then the pyrolysed produt was diluted with 50 mL of a NaOH solution (0,25mol L^{-1}) to obtain a GQDs nanoparticles dispersion. The electrochemical sensor was constructed using a composite of 1,0 mg mL^{-1}of CB, 300 µL mL^{-1}of GQDs dispersion and 1,0mg mL^{-1}of dihexadecylhydrogenphosphate in water. 6,0 µL of the as-prepared composite was dropped on the GCE surface, and dried at 50ºC. Transmission electronic microscopic(TEM) images of the GQDs-CB showed the presence of particulates on two scales, with smaller particles expected to be GQDs and larger particles expected to be CB. UV-vis absorption spectra of the GQDs showed a discreet absorption band with maxima wavelengthat 360 nm, associated with n->π* transitions of residual C=O bonds, and indicates the presence of GQDs in the dispersion. Cyclic voltammograms obtained using GQDs-CB/GCEpresented only a peak current, for EE2, at 0,8 V vs Ag/AgCl (3,0 mol L^{-1}KCl). The currentpeak intensity was 6 times higher than the current response obtained for bare GCE. Theelectroanalytical method was developed using a square wave voltametric technique and were analyzed samples of pharmaceutical formulations and lake water.

Green electrochemical sensors using CO2 Laser Pyrolysis on dehydrated green leaves substrates forguaiacol detection

Beatriz Fernandes Germinare[1], Jéssica Rocha Camargo[1], Bruno Campos Janegitz[1]

[1]Universidade Federal de São Carlos - Campus Araras (*DCNME*)

e-mail: beatrizgerminare@estudante.ufscar.br

The use of dehydrated green leaves as a substrate for manufacturing electrochemical sensors is an innovative approach that has the potential to provide a sustainable and eco-friendly alternative to traditional sensor substrates. CO2 laser pyrolysis enables the fabrication of precise, complex structures on various substrates, contributing to the development of high-performance, eco- friendly and cost-effective sensors. The green Leaf sensor has been optimized and standardized according to the laser cutter's setting possibilities, such as laser distance, potential and burning speed. In this sense, the leaves used for manufacturing electrochemical sensors were from S. macrophylla and P. Americana, tree species widely and easily found in Brazil [1,2]. The prepared system was used for the detection of guaiacol. Guaiacol It is widely used in medicine due to its potent antimicrobial, anti-inflammatory and analgesic properties. [3]. Indeed, the detection of guaiacol is important in several industries, including pharmaceutical, food, and environmental industries, for example, for quality control of drugs, to indicate the degree of wood smoke flavor in certain foods, or to monitor the level of the compound in air and water, as it can have adverse effects on human health at high concentrations. To this end, the work demonstrates a new system prepared with dehydrated green leaf substrate using CO2 laser pyrolysis for the detection of guaiacol.Acknowledgements: CAPES, CNPq and FAPESP (#grant 2017/21097-3, #grant 2019/23177-0, #grant 2023/00321-3).References:[1] NParks Flora Fauna We [Last updated on 06 April 2023].[2] Persea americana. e-mail: hitalo.silva@ufpe.br

Quantum dots (QDs) have aroused interest in the scientific community in recent years due to their distinct optical and electronic properties, being extensively studied for different types of applications. In view of their sensing properties, they have also been employed as sensors for ionic species, especially for heavy metals [1]. Bicarbonate ions (HCO_3^-) play a key role for aquatic life and the distribution of flora and fauna, being an important source of alkalinity and buffering in natural aqueous environments [2]. The detection of anionic species in an aqueous media is a challenge, as the polar nature of water weakens the interactions between sensors andions. Therefore, it is necessary to develop approaches capable of detecting HCO_3^- with high sensitivity. In this work, we used CdTe QDs as a fluorescent sensor for bicarbonate ions. CdTe QDs stabilized by cysteamine (CYA) were prepared in an aqueous media through a one-pot procedure. The CdTe-CYA QDs showed good optical properties and high photostability. The detection of HCO_3^- ions was studied in water, by adding the anions to the QDs suspension. The results showed a gradual enhancement in the QDs' emission intensity under subsequent HCO_3^- additions, demonstrating that CdTe-CYA QDs are sensitive to this anion. Thus, CdTe QDs present the potential to be used as fluorescent sensors to monitor anions in water sources.

Kombucha is a type of non-alcoholic beverage that is made through the fermentation of sweetened tea using a combination of bacteria and yeast [1]. It is crucial to monitor the fermentation products to ensure that the quality of Kombucha beverages remains consistent. This study demonstrates the use of an impedimetric electronic tongue (IET) to distinguish and quantify kombucha-fermented products such as ethanol, acetic acid, citric acid, and glucose. The IET consists of an array of interdigitated microelectrodes that are coated with layer-by-layer films of different nanomaterials such as gold, cerium oxide nanoparticles, and graphene oxide. By measuring capacitance and resistance values at 1 kHz, the IET can distinguish between kombucha samples of different flavors and brands and monitor the changes in flavor characteristics after opening the sample bottle. Using principal component analysis, the IET was able to quantify ethanol within a linear range of 0.1% to 1% v/v (R2 >0.99). This performance was comparable to the reference method (Anton Paar Alcoholizer 3001) at a 95% confidence level (t-Test). Additionally, the IET was also able to respond linearly to acetic acid, citric acid, and glucose in the range of 2.5-20 g L-1. Overall, the results demonstrate that the IET is a reliable and accurate tool for monitoring the fermentation products of kombucha. Acknowledgments: FAP-DF, CAPES and CNPq. References: [1] N. Synthesis of silica nanoparticles has been used in a wide variety of areas of knowledge due to the ease and its cost, thus facilitating their potential application in different areas, such as drug delivery systems, electronic devices, biofertilizers, and others. In agriculture, it allows overcoming several obstacles faced in the use of biofertilizers, such as reproducibility, dehydration, stability, andtemperature sensitivity. In this context, the association of nanostructured materials and bacteriathat promote plant growth (BPCVs) can be an efficient tool, increasing the potential of BPCVs as inoculants. The particle can be adjusted through the ratio between the amounts of TEOS and ammonia. However, mesoporous silica nanoparticles are difficult to detect inside plants, so it is necessary to combine them with some other easily detectable chemical element. One method to solve thisproblem was to introduce a detectable chemical element into the nanoparticle synthesis. Inthis work, the synthesis of silica nanoparticles was modified by introducing Ti(IV) isopropoxide (IPT) in the reaction medium. These nanoparticles were prepared with different s by adjusting the molar ratio between TEOS/NH_3 and TEOS+IPT/NH_3 to obtain $SiO_2$and SiO_2@TiO_2 nanoparticles. The aim herein was to evaluate the influence of the TEOSand IPT mixture on the final of the nanoparticles using factorial design techniques for experiments to later monitor the movement of these nanoparticles through the different tissues of the plants. The obtained nanoparticles were submitted to optical, spectroscopic, and structural characterizations and also to incorporation and release tests with dyes.

Influence of citrate concentration on AgNPs reductionfor SERS detection of the pesticide 2,4-D

Guilherme Dognani[1], Carlos José Leopoldo Constantino[1], Santiago Sanchez-Cortes[2]

[1]Universidade Estadual Paulista "Júlio de Mesquita Filho" - Faculdade de Ciências e Tecnologia - Campus de Presidente Prudente, [2]Instituto de Estructura de la Materia - Consejo Superior de investigacion Científica

e-mail: dognani.g@gmail.com

The environmental pollution concern has been intensified due to consumer demand. New pesticides have been incorporated into daily agriculture to achieve higher production and a shorter time to harvest. In this sense, pesticides can be present as a residual contaminant in our food, soil, and water [1]. Alternatives to detect pesticides in different matrices have been developed and studied, seeking more reproducibility and signal accuracy. Surface- enhanced Raman scattering (SERS) has emerged as an alternative to detect pesticides inlow concentrations exhibiting signal accuracy [2]. However, the detection of certain challenging molecules such as 2,4-Dichlorophenoxyacetic acid (2,4-D) has proven to be difficult due to its highly electronegative nature and carboxylic groups, which makes it less responsive [3]. Herein, the citrate effect on the silver reduction applied in the quantitative analysis of 2,4-D by SERS was evaluated. AgNPs were synthed using citrate as a reduction agent at a concentration of 1% (w/w) ($AgCit_{1.0}$), 0.5% ($AgCit_{0.5}$), and 0.25% ($AgCit_{0.25}$). The decrease of citrate molecules present on the AgNPs surface increases the interaction of the analyte, leading to a limit of detection (LOD) of 1.46 $x10^{-9}$mol/L, while the normal synthesis ($AgCit_{1.0}$) decrease significantly the ability to detect this analyte, leading to a higher limit of detection (1.58 $x10^{-7}$mol/L). In this context, the study of the surface chemistry of plasmonic nanoparticles applied on SERS becomes essential for the efficiency of detection and quantification of the desired analyte.

Influence of Oxygen Concentration in RF-Magnetron Sputtering Deposition Atmosphere on ZnO/CuO Nanocomposite Gas Sensors

Weverton Alison dos Santos Silva[1], Bruno Sanches de Lima[2], Maria Inês Basso Bernardi[1], Valmor Roberto Mastelaro[1]

[1]University of São Paulo (*São Carlos Institute of Physics*) , [2]University of Campinas (*Gleb Wataghin Institute of Physics*)

e-mail: wevertonalison@gmail.com

Nanostructured materials based on metal oxide semiconductors (SMOx), such as ZnO and CuO, offer great potential in the development of gas sensors due to their high sensitivity and response and recovery times. However, challenges remain in improving their selectivity and lowering the operating temperatures. The sensing performance of these materials can be tailored by controlling factors such as morphology, particle , defects, and carrier density through the synthesis process[1]. In this study, we explored the effect of varying the deposition atmosphere on the gas sensing properties of ZnO/CuO nanocomposites fabricated using the RF-Magnetron Sputtering technique. The materials were characterized by X-ray diffraction (XRD), UV-Vis spectroscopy, scanning electron microscopy (SEM), Mott-Schottky analysis, and X-ray photoelectron spectroscopy (XPS). Our results demonstrate that the concentration of oxygen (O2) in the deposition atmosphere plays a crucial role in modulating the sensing properties the ZnO/CuO for different gases. This work contributes to the understanding of the relationship between deposition parameters and the sensing performance of ZnO/CuO-based gas sensors, paving the way for the development of more efficient and devices.

Influence of sample preparation method on Ag colloid aggregation and consequences to carbendazim detection via Surface-Enhanced Raman Scattering (SERS)

Isabela Bianchi Carvalho[1], Cibely da Silva Martin[2], Tatiana Aparecida de Oliveira[2], Marcelo José dos Santos Oliveria[2], Carlos José Leopoldo Constantino[2]

e-mail: isabela.bianchi-carvalho@unesp.br

Faced with the impossibility of finding a safe dose for human consumption, the use of the fungicide carbendazim (MBC) was prohibited by ANVISA in 2022. Therefore, the detection and monitoring of MBC is of great importance. Among the existing techniques, SERS has often been used for the detection of pesticides. In this work, it was evaluated the influence of sample preparation on Ag colloid aggregation and, consequently, on MBC detection via SERS. The sample preparation was performed by using standard addition (SAM - successive additions of MBC solution to the same Ag colloid dispersion) and external addition (ESM - a neat Ag colloid dispersion for every aliquot of MBC solution) methods. For SERS measurements, the detection was made at similar concentrations for both methods (1.3x10-6 mol/L). For SAM, the best signal/noise ratio occurs at 4x10-6 mol/L and decreases after this. For ESM, it decreases just after 1.3x10-6 mol/L. In the extinction measurements, for ESM, the appearance of the aggregate band occurs in a concentration close to that by SAM (1.3x10-6 mol/L) with an offset in maximum intensity depending on MBC concentration, suggesting differences in the morphology of the aggregates [1]. In the study of the size distribution by DLS (dynamic light scattering), there is a more pronounced displacement for larger sizes at 1.3x10-6 mol/L for ESM. By SAM, it happens more continuously. For zeta potential measurements of Ag colloid as a function of MBC concentration for both methods, the values become less negative, indicating a probable aggregation of AgNPs, with the chloride ions surrounding the AgNPs being replaced by MBC molecules. In conclusion, ESM and SAM methods showed similar results for SERS in terms of spectra in function of MBC concentration, despite the differences found for DLS and UV-Vis.

e-mail: billdarwin08@gmail.com

We present the study of CuO thin films grown using a DC magnetron sputtering. Firstly, Cu thin films were deposited during 1 min onto borosilicate glass substrate using a metallic Cu target. After that, a thermal annealing at 500°C during 2h in air atmosphere were carriedout to obtain the CuO films. Films with different thicknesses were obtained by changing thepower (100, 150, 200, 250 and 350 W) of the power supply. X-ray diffraction (XRD) dataanalysis confirmed the CuO phase formation, without any evidence of extra phases. XRDdata analysis indicate that the crystallite increases from 39 nm to 54 nm as the power source is increased from 100 to 350W, respectively. Furthermore, the residual strain showslarger value for the thinner film, which has been assigned to the structural disorder due tothe strong film-substrate interaction. The unit cell volumes vary in the range 81.36 to 81.24$Å^3$, which is larger than that expected for bulk CuO (81.08 $Å^3$) [1].Cross-section scanning electron microscopy images indicate a growth rate of (3.6±0.2) nm/W and the film thicknessvary from 256 to 1231 nm when the power vary from 100 to 350 W, respectively. Ramanspectroscopy measurements evidenced the presence of only canonical modes associatedwith CuO crystalline phase [2], confirming the results obtained from XRD data analysis. Additionally, UV-Vis spectroscopy measurements revealed a band gap energy (E_g) varyingfrom ~1.74 eV to ~1.41 eV with the power of the power source. That band gap energy reduction trends were assigned to the structural disorder decrease with the film thickness. Tests of gas sensitivity were carried out using methane gas (NH4) at different working temperatures (323K-473 K). Results indicated that the better sensor response was obtainedfor the thinner film. It was associated with the smaller grain for this thinner film in comparison to the others [3]. These results suggest that the CuO thin films are promisingfor potential sensing application.

ISOTHERMAL AMPLIFICATION AND NANOGOLD: GOLD NANORODS AS BIOSENSOR COUPLED TO LAMP TECHNIQUE FOR OPTIMIZATION

Amanda Bonoto Gonçalves[1], Letícia Trindade Almeida[2], Iara Apolinário Borges[3], Livia Siman Gomes[3], Kennedy Batista[3], Pedro Augusto Alves[4], Rosimeire Barcelos[3], Caroline Magalhães Junqueira[3], Rubens Lima do Monte Neto[4], Anna Carolina Pinheiro Lage[2]

e-mail: amandabonoto@gmail.com

Loop Mediated Isothermal Amplification (LAMP) is a promising genetic material amplification technique that offers advantages such as high specificity, isothermal amplification, reduced reaction time and no need for complex laboratory equipment[1,2]. Gold nanoparticles (AuNPs) are also of interest in the diagnostic innovation scenario due to their excellent performance as biosensors, owing to their unique physicochemical properties[3]. Their versatile surface chemistry allows them to be easiy bioconjugated with a wide range of molecules, making them excellent signal transducers in the construction of biosensors[3]. The objective of this work was to develop a rapid, specific, and sensitive test for the detection of the SARS-CoV-2 virus using biosensors consisting of AuNps conjugated with specific DNA probes that recognize the material amplified by a RT-LAMP reaction and this approach was named iAnG (Isothermal Amplification and Nanogold)[4,5]. RT-LAMP reactions were performed for 15 minutes at 65ºC, using the WarmStart® Colorimetric LAMP 2× Master Mix [NEB #M1804] and N gene as the target. AuNps were synthed as nanorods and conjugated with a probe designed to recognize a specific region of SARS-CoV-2 N gene. The biosensors were titrated with LAMP reaction products and results observed in a UV-Vis Spectroscopy and dynamic light scattering device. UV-Vis analysis showed shifts in the longitudinal plasmon resonance peaks for positive controls, while negative control's sensors had their absorption spectrum disintegrated. In dynamic light scattering, differences in tau parameter was clearly observed between negative and positive samples and graphs showed different patterns for each control. Results showed an efficient proof-of-concept for iAnG test detecting the genetic material of SARS-CoV-2, and it was possible to reduce the RT-LAMP reaction time from 40 to 15 minutes. In conclusion, iAnG technique could be a promising approach for rapid ans sensitive diagnosis.

Lab-made conductive ink for the production of immunosensors for α-synuclein detection in different matrices

Luiz Otávio Orzari[1], Luiz Ricardo Guterres e Silva[2], Rafaela Cristina de Freitas[1], Laís Canniatti Brazaca[3], Bruno Campos Janegitz[4]

e-mail: l.o.orzari@gmail.com

Lab-made conductive inks are interesting alternatives for electrode materials, as they present advantages such as their inherent relative low cost and ease of preparation and use [1]. Among neurological diseases, Parkinson's is one of the most common, which appears with the loss of pigmented dopaminergic neurons in the substantia nigra and accumulation/deposition of α-synuclein in the brain, making its detection of clinical interest for early diagnosis [2]. Here we present the development of a carbon black and poly(vinyl alcohol) glue conductive ink and its application as an electrochemical biosensing of clinical interest analytes. The ink was prepared by mixing the two components in a dual asymmetric centrifuge. After, electrochemical sensors were produced, which were morphologically and electrochemically characterized by techniques such as scanning electron microscopy and cyclic voltammetry. Pd nanoparticles were electrodeposited over the proposed sensor. This procedure was explored and optimized with different experimental designs. The sensors were then further modified with proper and specific antibodies for the analytical detection of α-synuclein, by electrochemical impedance spectroscopy. Two calibration curves were obtained with such material: the first in phosphate buffer, where the linear behavior was acquired between the concentration of 1.5 and 15 μg mL^{-1}, with a calculated LOD of 0.13 μg mL^{-1}; and the second one, where the linear range was observed from 6.0 to 100.5 μg $mL^{-1}$of a-synuclein, with a LOD = 1.31 μg mL^{-1}. The ink is easy to prepare and use, and the produced devices demonstrated attractive results for the clinical diagnosis of neurological diseases related to α-synuclein, both in simple and complex sample matrices.

e-mail: paulo_vitor_d_morais@hotmail.com

Nanostructured materials have demonstrated significant potential for applications in the field of (bio)sensing. Among these, the capacitive electrolyte-insulator-semiconductor (EIS) sensor is a suitable field-effect device for nanostructured films integration as sensing units [1,2]. In this work, we investigate the fabrication of a hybrid nanostructured film using the layer-by-layer (LbL) technique combining cobalt ferrite ($CoFe_2O_4$) nanocrystals dispersed in poly(vinylpyrrolidone) (PVP) and poly(amidoamine) (PAMAM) dendrimer. LbL films containing a PAMAM/PVP-$CoFe_2O_4$ architecture with different bilayers were fabricated onto EIS chips of Al/p-Si/SiO_2. The morphology of the films was characterized by atomic force microscopy (AFM), and the sensing performance toward H_2O_2 detection evaluated by capacitance-voltage (C/V) and constant capacitance (ConCap) measurements. The surface of a 3-bilayer film observed in the AFM images exhibited a homogeneous distribution with random distribution of spherical-shaped agglomerates identified as Co_2FeO_4 nanocrystals with diameters ranging from 20 to 40 nm. Films with different bilayers were also analyzed by AFM microscopy, showing that for higher bilayers a homogeneous pattern of nanocrystal distribution was not observed. Analyzing the electrochemical and morphological characteristics of the films, we found an optimized system. The results indicated the best performance toward H_2O_2 exhibited by 3-bilayer EIS-(PAMAM/PVP-$CoFe_2O_4$) sensor, which presented a sensitivity of 26.5 mV decade^{-1} and a low limit of detection of 157 µM. The possible overall mechanism that may explain the operating principle of the EIS-$CoFe_2O_4$ sensor is assigned to the catalytic activity of $CoFe_2O_4$ nanocrystals toward H_2O_2 [3]. The set-up achieved in this work, a field-effect sensor for H_2O_2 detection, appears as an alternative to conventional amperometric H_2O_2 sensors.

Low-cost and portable colorimetric biosensor is produced for the diagnosis of viral diseases as a point-of-care tool

TATIANNY DE ARAUJO ANDRADE[1], Jemmyson Romário de Jesus[2], Paulo de Tarso Garcia[3]

The frequent outbreaks of infectious diseases around the world have presented significant challenges to health systems, requiring the development of rapid and accurate diagnosis devices for effective monitoring and control in remote areas [1]. In this study, a low-cost and portable biosensor based on cellulose paper with specific antigen (IgG) conjugated to gold nanoparticles (AuNPs) is produced for the diagnosis of viral infections, using a smartphone as a detector. AuNPs were synthed and characterized using specific techniques (UV-Vis, FTIR, TGA, and MET). A 23 factorial design was then employed to optimize the conditions for conjugating AuNPs with the IgG antibody (AuNP@IgG). Three factors were evaluated: (1) concentration (50-320µg.mL-1), temperature (4-37°C), and pH (5-9). As results, the AuNPs were successfully obtained with particle of ~90 nm, and spherical morphology, as indicated by MET imaging. The response surface analysis indicated the optimal conditions for the IgG conjugation to AuNPs, with a concentration (360 µg.mL-1), temperature (25ºC),and pH (7.4). Currently, the impregnation studies of AuNP@IgG onto cellulose paper andthe optimization detection system using smartphone (PhotoMetrix App) are being investigated, and the findings will be presented at the event.

Luminescent gold nanoclusters obtained by pulsedlaser ablation in water: modulation of the photoluminescent response by the interaction withheavy metal ions

Sensitive sensors for the detection of heavy metal ions (HMI) in water are in high demand, due to the danger they represent for both environment and human health. We report different simple, green and cheap experimental methods for the separation of luminescent gold nano-clusters (AuNCs) from a pristine colloidal dispersion of gold nanoparticles (AuNPs) obtained by pulsed laser ablation (PLA) in water. Independently on the separation technique, the bleached material present both UV and blue emission, a concentration less than 1 ppm, a negative charge, and dimensions ranging from 0.5 to 2.5 nm, as evidenced by high resolution electron microscopy. The bleached AuNCs colloids were used as luminescent chemosensors for the detection of Cd^{2+}, Pb^{2+}, $Hg^{2+}$and methyl mercury $CH3Hg^{+}$ions in water. The intensity of blue emission decreased (no more than 10%) and saturated at concentrations higher than 20 ppb for all the heavy metal ions tested. In contrast, the UV band emission was remarkably affected in the presence of Hg^{2+}ions, thus leading to signal variations for concentrations well beyond 20 ppb (the concentration at which saturation occurs for other ions). The limit of detection for $Hg^{2+}$is about 3 ppb (15 nmol/L), and the photoluminescence intensity diminishes linearly by about 75% up to 600 ppb. The results are interpreted based on the ligand-free interaction, i.e., the metallophilic bonding formation of $Hg^{2+}$and Au^{+}oxide present on the surface of the UV-emitting nanoclusters [1].

Metal-organic frameworks (MOFs) are porous coordination polymers designed based on the variety of the metal coordination environment and the nature of the organic ligand to form a network [1]. These materials have attracted research interest due to their promising applications. However, their use as electrochemical sensors is rare due to their poor electrical conductivity. In this sense, MOFs have been tested as carbon paste electrode (CPE) modifiers. The sp^2 carbons and the presence of six-membered aromatic rings in the graphite structure allow electrical conductivity when forming composite. This is provided by structural changes in the surface area of MOF. The sensing capability of a Fe^{III}OFs was used for detecting of Cu^{2+} in ethanol (EtOH). Cu^{2+} can be incorporated into EtOH due to the intensive use of pesticides in sugarcane plantations. PXRD and FTIR were employed to characterize the synthesized MIL-88b-NH_2 and MIL-82 structural features. According to the results, both MOFs were successfully obtained. MIL-88b-NH_2/CPE was chosen to be tested as a Cu^{2+} sensor in EtOH based on CV result. Thereafter, SWASV was used to quantify the Cu^{2+}. The analytical signal of the electrode showed good stability (RSD = 5.2%). The peak current of MIL-88b-NH_2/CPE gradually increased with the addition of Cu^{2+}. Furthermore, r and R^2 were equal to 0.9993 and 99.85%, respectively, with a LOD = 0.020 μmol L^{-1}. Our findings indicate MIL-88b-NH_2 modified CPE in an appropriate sensor for evaluating EtOH by Cu^{2+}.

This work developed a sensor for diagnosis of COVID-19 using screen-printed electrode (SPE) electrochemically modified by MIP using pyrrole (Py) as monomer and the spike protein (S-protein) as template, named MIP-PPy. The number of cycles used in the electropolymerization and the monomer and template concentrations were optimized.[1] Template removal was performed using a 10% (w/v) HAc solution and 0.2% (w/v) sodium dodecyl sulphate for 2 h. The thickness of the optimized sensors was estimated by SEM analysis. A pre-concentration step applying +0.6V potential for 1 min was performed to achieve detectability on a fentrogram scale. The sensor was also subjected to tests of specificity, stability over 21 days, and analysis of clinical samples. The sensor response for S-protein was done by indirect determination using probe $[Fe(CN)_6]^{3-/4-}$ by differential pulse voltammetry technique. The best conditions were defined as pyrrole at 0.3 mol/L, S-protein at 40 μg/mL, and 4 cycles. SEM images confirmed the formation of the polymeric film since MIP-PPy showed a greater thickness compared to the NIP-PPy (non-printed sensor) and the bare SPE. Under optimized conditions, rebinding assays after the pre-concentration step using 100 fg/mL of S-protein in PBS (pH 7.4), showed a decrease in probe current when using MIP-PPy regarding the NIP-PPy ones. Such behavior reveals the selective interaction of the S-protein with the imprinted cavities. The sensor showed good specificity. The electrochemical response of MIP-PPy reduced 15% of its initial value after 14 days, showing intermediate stability. Sensor validation with saliva samples showed agreement with RT-PCR results. Therefore, the developed sensor proves to be a great alternative method to RT-PCR, featuring good detectability, fast analysis time, specificity, portability, and simplicity of synthesis.

2-Butanone is one of the most essential ketones in the industry due to its use as a solvent in paints, pharmaceuticals, adhesives, cosmetics, etc. [1]. Besides, patients with lung cancer exhale 2-butanone in their breathing [2]. Therefore, a 2-butanone sensor could be applied in indoor air quality monitoring and non-invasive diagnosis of diseases. In this work, we developed a synthesis of Co_3O_4 using the ZIF-67 precursor with a typical method [3] and applied heat with a microwave (2,5 GHz, 800 W) to speed up the synthesis process. Firstly, a mixture was made using an aqueous solution of 0,45 g of $Co(NO_3)_2.6H_2O$ and 5,54 g of 2-methylimidazole. The resulting solution was stirred, placed in a polytetrafluoroethylene autoclave, and heated at 100 °C for 30 min in the microwave. Then, the purple precipitate of ZIF-67 was centrifuged, washed with ethanol, and dried at 80 °C overnight. ZIF-67 was calcinated at 300 °C for 1 h at a heating rate of 5 °C min^{-1} to produce the Co_3O_4. The sampleswere characterized by XRD, TGA and FESEM. The sensor measurements were carried out atan operating temperature range of 250-450 °C with 100 ppm of 2-butanone, methanol, 2-nonanone, benzene, toluene, and m-xylene. The Co_3O_4 sensor showed a higher response for 2-butanone.

Microbial Volatile Organic Compounds (MVOCs) are produced during the metabolism of fungi and bacteria, which causes several health problems in humans [1]. 3-methyl-1-butanol (3M1B) is an MVOC produced by Pseudomonas spp. and a spoilage indicator of seafood [2]. Detecting the 3M1B is extremely important to bring a better quality of our food. The heterojunction n-p of ZnO and Co_3O_4 was produced from Metal-Organic Framework (MOF). In this work, we developed a synthesis of ZnO/Co_3O_4 using ZIF-8/ZIF-67, adapting a typical method [3]. Firstly, 151 mg of ZIF-8 was dissolved in deionized water, stirring for 30 min, and 62,4 mg of 2-methylimidazole was added. After that, a mixture was made using 5,2 mg of $Co(NO_3)_2.6H_2O$ in an ultrasonic spray. The resulting solution was stirred for 6 h, centrifuged, washed with ethanol, and dried at 80 °C for 20 h. Then, the ZnO/Co_3O_4 was produced by calcinating the ZIF-8/ZIF-67 at 450 °C for 2 h at a heating rate of 2 °C min^{-1}. The samples were characterized by FESEM, XRD, and TGA. Sensor measurements were conducted at different operating temperatures with 100 ppm of 3M1B, 2-butanone, 2-nonanone, m-xylene, toluene, methanol, and benzene. Finally, the sensor showed a higher response for 3M1B at 350 °C.

Multivariate optimization of electrochemically reduced graphene oxide films synthesized from electronic waste for the voltammetric determination of β-estradiol

Bruna Santos de Castro[1], Gabriel Henrique Sperandio[1], Leonardo Luiz Okumura[1], André Fernando de Oliveira[1], Renata Pereira Lopes Moreira[1], Tiago Almeida Silva[1]

[1]Fundação Universidade Federal de Viçosa (*Departamento de Química*)

e-mail: bruna.s.castro@ufv.br

The use of reduced graphene oxide as an electrode modifier material is increasing due to its high surface area and electrocatalytic activity [1]. Conditions of electrochemical reduction are crucial to control the extent of the process. Total reduction can be unwanted because itcan increase the background current and decrease the sensitivity due to the reduced number of oxygenated groups [2]. In this study, factorial design was applied to promote the multivariate optimization of the electrochemical reduction of GO films to enhance the voltammetric response of β-estradiol hormone. GO was synthed by the modified Hammers method using graphite recovered from discharged batteries. Cyclic voltammetry was used to carry out the electrochemical reduction of GO films, which were prepared by the drop casting method using a glassy carbon electrode (GCE). The factorial design used was quadratic with three variables at three levels, as follows: scan rate (ν = 10, 50 and 90 mV s^{-1}), number of cycles (5, 10 and 15) and GO concentration at the aqueous dispersion (0.5, 1.25 and 2.0 mg mL^{-1}). Data analysis was performed in Statistica® software. The matrix with parameters combinations generated 11 assays. The voltammetric profile of the $Fe(CN)6^{3-/4-}$redox probe and the anodic peak current of β-estradiol were recorded and usedas the factorial design response. Thus, it was possible to relate the rate of film reduction with the voltammetric response of β-estradiol. Scan rate was the parameter that influenced the most, as well as its interaction with GO concentration. The optimal conditions were ν = 90 mV$s^{-1}$and c(GO) = 0.5 mg mL^{-1}. On the contrary, the number of cycles did not influence significantly, which allowed the choice of the lowest value (5) for subsequent studies.

Hematological neoplasms, commonly called liquid tumors, constitute a heterogeneous group of pathologies. In acute promyelocytic leukemia, the PML/RARα chimeric oncogene is a striking feature, resulting from balanced reciprocal translocation involving the PML gene and the retinoic acid alpha receptor. Although the techniques commonly required in clinical practice prove to be effective for the diagnosis of the PML/RARα fusion gene, they have important limitations. Among these factors, the extensive analysis time and high costs can be highlighted [1]. The aim of this study is to develop a nanobioelectrode based on conductive polymer and gold nanoparticles applicable to the diagnosis of the PML/RARα chimeric oncogene. To characterize the construction stages of the sensing platform, the techniques of cyclic voltammetry and electrochemical impedance spectroscopy were used. In the last stage of platform assembly, through the immobilization of DNA sequences on the surface, it was possible to obtain a modified electrochemically active area for the biorecognition assays [2]. Upon exposure of the genosensor to positive plasmid samples, a decrease in the anodic and cathodic peak currents was observed, as well as an increase in resistance to charge transfer. Thus, the developed genosensor proved to be an efficient tool for identifying the PML/RARα oncogene and monitoring patients during treatment.

Palladium deposition on conductive ink of carbon nanotubes for the construction of an electrochemical immunosensor

Jefferson Henrique de Souza Carvalho[1,2], Bruno Campos Janegitz[3]

[1]Universidade Federal de São Carlos – Campus Sorocaba, [2]Universidade Federal de São Carlos – Campus Araras, [3]Universidade Federal de São Carlos – Campus Araras (*DCNME*)

e-mail: jeffersoncarvalho@estudante.ufscar.br

Among the new technologies capable of assisting in the determination of biomarkers of various diseases, electrochemical immunosensors stand out. Such devices gain notoriety in the field of medicine due to the possibility of responses in a shorter time, high sensitivity and aid in diagnosis in the early stages[1]. An alternative for the manufacture of these devices are conductive inks, contributing to a system with different architectures, relatively low cost and possible to be manufactured in the laboratory[2]. Thus, in this study we present the first results obtained for an electrochemical sensor of conductive carbon nanotube ink, deposited on a paper substrate. A study was carried out to waterproof the paper, modifying it with beeswax. Palladium deposition after making the sensor is a study that precedes immunosensor immobilization stages for biomarkers of neurodegenerative diseases. Electrochemical (cyclic voltammetry and electrochemical impedance spectroscopy) and morphological (scanning electron microscopy (SEM) and Fourier transform infrared spectroscopy (FTIR)) characterizations were used. The concentration of the beeswax/hexane solution for waterproofing the paper was 1g/100 mL. In the SEM images, it was possible to observe a layer capable of covering the pores of the paper is observed, guaranteeing the waterproofing of the substrate. Also, the proposed sensor was modified with Pd particles, which occurred after electrodeposition of the metal by chronoamperometry. The time studied for electrodeposition ranged from 1 to 5 minutes, with 5 minutes being chosen as ideal. To stabilize the particles on the surface, cyclic voltammetry at 50 mV $s^{-1}$was applied. This paper analytical device is an alternative for the development of electrochemical sensors and biosensors.

Physical-chemical characterization of biochar from cupuassu bark (Theobroma grandiflorum) for application as a soil conditioner

Vera Lucia da Silva Marinho[1], Ruana Pontes Fonseca[1], Taís Aimê Azevedo Garcia[1], Marcely Vieira da Costa[1], Jakson Douglas Rocha de Albuquerque[1]
Federal Institute of Education, Science and Technology of Amazonas,Parintins, Amazonas, Brazil

e-mail: veramarinho34@ifam.edu.br

Abstract: Biochar is the product of pyrolysis of renewable biomass, with low oxygen availability. This material is very porous, rich in carbon and contains a large amount of organic structures and inorganic elements. The chemical composition of the ash fraction consists of macro and micronutrients for plants and improves soil fertility conditions. The objective of this research was to carry out the physical-chemical characterization of the cupuaçu bark biochar, identifying its physical properties favorable to its use as a soil conditioner. The *Theobroma grandiflorum* peels used as raw material was purchased from farmers and fairgrounds in the municipality of Parintins. The synthesis of biochar for physicalchemical and morphological characterization was carried out using the activating agent phosphoric acid (H_3PO_4) in a ratio of 1:1 by mass. The physical and chemical characterization by X-Ray Diffraction Technique (DRX) was performed at Federal Institute of Amazonas, Campus Manaus Centro and the morphological one by Scanning Electron Microscopy (SEM) at INPA's Optical Microscopy Laboratory. It can be concluded that the lower temperature in the fast pyrolysis influences the formation of larger pores. This may indicate that the raw material of the samples was thermally decomposed during the pyrolysis process, as expected, and that the obtained biochar has a high capacity for nutrient and water retention.
Keywords: biochar, nutrient, retention, soil conditioner, water.

Introduction

Biochar is a product of the thermal decomposition of organic materials under low oxygen availability. The chemical composition of the ash fraction consists of macro and micronutrients for plants and improves soil fertility conditions. Biochar can be obtained from different plant species and its application as a soil conditioner has caused an increase in crop productivity in degraded soils (LEHMANN; JOSEPH, 2009 apud RIBEIRO, 2016). The objective of this work is to characterize physically and mologically the biochar from *Theobroma grandiflorum* peels evaluating its application as a soil conditioner in the development of lettuce seedlings

Experimental Procedure

The *Theobroma grandiflorum* used as raw material was purchased from farmers and fairgrounds in the municipality of Parintins. The synthesis of biochar for physical-chemical and morphological characterization was carried out using the activating agent phosphoric acid (H_3PO_4) in a ratio of 1:1 by mass. The procedure consisted of impregnating the cupuaçu peels with activanting agent under constant agitation for 5 h and then, dried in an oven at 105 °C for 12 h. The resulting material was carbonized and activated in porcelain crucibles. The procedure was carried out in a muffle furnace with the following heating steps: 115 °C for 30 min, 360 °Cfor 30 min and 500 °C for 1 h. Biochar samples were synthesized by changing the temperatureof the last heating step to 400 °C. The obtained biochars were washed with distilled water at 80 °C. After washing, all samples were dried at 105 °C for 12 h. All samples were obtained in triplicate. The physical and chemical characterization by X-Ray Diffraction Technique (DRX) was performed at Federal Institute of Amazonas, Campus Manaus Centro and the morphological one by Scanning Electron Microscopy (SEM) at INPA's Optical Microscopy Laboratory.

Results and Discussion

Fig. 1 presents the X-ray diffractograms obtained for the biochar samples synthesized at 400°C and 500°C. It is possible to observe that the samples have an amorphous structure, characterized by the wide peak in the 2θ position from 10° to 30° C. In the case of amorphous materials, the diffraction patterns do not produce narrow peaks as in crystalline materials, but wider peaks, because the arrangements of atoms are irregular (Kahn, 2007). The amorphous peak is attributed to the presence of carbon.

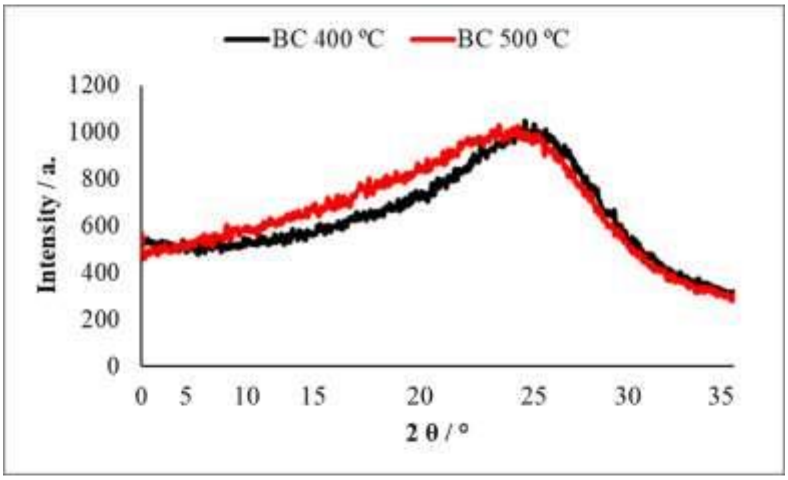

Figure 1: Biochar diffractogram synthesized at 400°C (black curve) and 500°C (red curve).

The micrographs of biochar synthesized at 400°C and 500°C, Fig.2 (A, B, C and D), show the morphology of the material. It is possible to identify that the surfaces are porous. Figures 2 A and C corresponding to the biochar synthesized at 400°C show larger pores than the biochar synthesized at 500°C. It can be concluded that the lower temperature in the fast pyrolysis influences the formation of larger pores. This may indicate that the raw material of the samples was thermally decomposed during the pyrolysis process, as expected, and that the obtained biochar has a high capacity for nutrient and water retention.

At 45 DAS it was verified that the height of the lettuces presented very close values and the widths had significant differences. The lettuce leaves treated with biochar had greater widths than the control and among the proportions used, the dose of 30% provided wider leaves. This can be attributed to the ability of biochar to help retain nutrients. Júnior et al. (2012) verified that biochar, produced in a masonry oven, at a dosage of 15% to the substrate, was a good alternative as a conditioner in the production of lettuce seedlings.

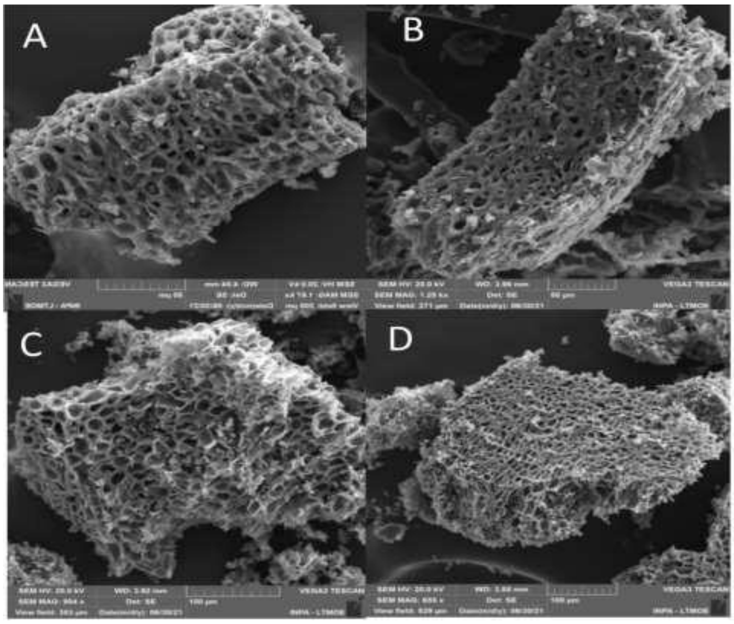

Figure 2: Micrographs of biochar synthesized at a temperature of 400°C (A and C) and 500°C (B and D).

The performance of lettuces in relation to the number of leaves as a function of the BC showed a difference only in the proportion of 30% of biochar, the other proportions had the same number of leaves as the control, as shown in Tab. 1. Regarding the larger leaf, it was also detected that the soil with 30% of biochar showed better growth whose look reached a length of 15.5 cm, showing a superiority of 2 cm over the control. Cavalcante et al. (2012) detected the positive influence of biochar on the formation of yellow passion fruit seedlings as the increase in the proportion of biochar in the substrate up to a concentration of 50%.

Conclusions

The biochar produced by hand with *Theobroma grandiflorum* bark in a proportion of 30% showed better results than the other proportions in relation to height and number of leaves. The other proportions had equal and lower results than the control. Thus, biochar from *Theobroma grandiflorum* bark can be a viable alternative as a material for improving the substrate in the production of vegetables. To confirm the results, further studies are needed.

Preparation of mango (*Mangifera indica* L.) waste flour for the application of Cu^{2+} removal in an aqueous medium by adsorption process

Fernanda Kelly Alves de Souza[1], Aroldo Geraldo Magdalena[1], Maria Laura Della Costa Silveira[1], Luis Fernando Rocha Cunha Lemes[1]

[1]Universidade Estadual Paulista (*Faculdade de Ciências de Bauru*)

e-mail: fernanda.a.souza@unesp.br

Contamination of water by Cu2+ harms the environment and human health.[1] Adsorption reduces the concentration of these ions.[1,2,3] The material most commonly used in adsorption is activated carbon, but this can be replaced by biosorbents, materials derived from agroindustrial waste biomass that are available, accessible, renewable, and recyclable.[1] The flour from the residue of mango (Mangifera indica L.) is a biosorbent capable of adsorbing Cu2+.[1] This study aimed to verify the efficiency of Cu2+ adsorption using mango waste flour. The preparation of MWF consisted of drying the cores and seeds of Tommy mangoes (80°C, 48 hours), crushing, sifting, and treatment with HCl (0.05mol.L-1, 10minutes);[1,3] MWF was characterized with FTIR and point of zero charge;[1,3] The adsorption studies were conducted at room temperature, pH 4 and agitatio [3] The parameters to determine the optimal adsorption conditions were adsorption time and MWF ma [3] The final concentration of Cu2+ was determined by complexometric titration. FTIR identified organic groups that interact with Cu2+;[3] The point of zero charge (PZC) determined that at a pH 4.3, the charge on the MWF surface is neutral; thus, at a pH lower than 4.3, the charge is positive and interacts with anions, and at a pH greater than 4.3, the charge is negative and interacts with catio [1] The optimal adsorption conditions were 30minutes and 0.1g of MWF; The linearized Freundlich and the non-linearized Redlich-Peterson adsorption isotherm models were found to be more suitable for this adsorption, suggesting a multilayer adsorption mechanism of MWF;[3] The maximum percentage of Cu2+ removal was 77.48%. Thus, this adsorption process using MWF has the potential for removing Cu2+.

The production of disposable screen printed electrochemical sensors (SPCEs) is highlighted in Electrochemistry, due to its advances such as low cost, sample volume reduction, miniaturization, mass production and portability [1, 2]. In addition, disposable printed electrodes overcome the problem of poisoning the surface of the working electrode due to their single-use possibility. In this work, a new self-manufactured conductive ink was developed from graphite powder as a conductive material, and a commercial glue based on polyvinyl acetate (PVA), originally used for craft purposes, as a polymeric vehicle, with the addition of solvents, acetone, ethyl acetate, and glycerin as additives. To obtain a flexible device, the substrate chosen for this purpose for the production of the sensor was the aromatic aliphatic copolyester EcoflexTM. SEM, FTIR, contact angle electrochemical impedance spectroscopy and voltammetry, carried out the morphological characterizations. The developed electrochemical sensor was applied for detection of paracetamol, using square wave voltammetry in the range from 7.0 to 100 µmol $L^{-1}$and with detection limits of 1.4 µmol L^{-1}. The sensor was suitable for rapid detection of paracetamol in artificial sweat and syrup samples with recovery between 90 and 108%. Therefore, it was possible to develop a low-cost screen-printed electrochemical sensor with satisfactory analytical response.

During the COVID-19 pandemic, antibody-based rapid tests were democratized as the World Health Organization's main strategy to control the spreadof the SARS-CoV-2 virus and monitor its transmission. But even after pandemic control, immunochromatographic tests are still of importance in post-infection and immunological surveillance. However, regulatory agencies and healthcare managers have reported this method's poor sensitivity and reliability. Hence, improving detection methods is recommended as means to achieve high sensitivity. This work devised a technique that combines surface-enhanced Raman spectroscopy (SERS) with artificial intelligence tools to improve the accuracy, sensitivity, and reliability of the results. To do so, gold nanoparticles were synthed, characterized (UV-Vis, MET, DRX, DLS, FTIR, and Raman), and functionalized with an antigenic fragment ofthe recombinant spike protein. The spectra of 594 blood serum samples were obtained bythe Raman spectrometer Metrhom Mira XTR. Feature extraction techniques such as PCA[1], kPCA[2], t-SNE[3], and UMAP[4] were used to classify the spectra, coupled with a range of machine learning algorithms including kNN, SVM, and DT. The new system was comparedtothe standard ELISA technique and exhibited an average sensitivity of 95.8% ands pecificity of 90.8%. These findings are crucial in paving the way for a new generationof nanosensors that are highly versatile, reliable, and sensitive.

The monitoring of amines emitted from food degradation, such as trimethylamine (TMA), is important to ensure food quality [1]. A promising way to monitor such compounds is through the development of gas sensors, in which the choice of the sensing material is key to the sensor' s performance. Graphene quantum dots (GQDs) is a promising material for this end, due to their multiple active sites for interaction with gaseous analytes [2]. In this work, we evaluated theoretically and experimentally the adsorption of TMA onto GQDs functionalized with different oxygen functionalities, namely hydroxyl (GQDs-OH), epoxy (GQDs-Ep), and carboxyl (GQDs-COOH) groups. Density functional theory (DFT) calculations were performed with the M06-2X functional with the 6-31+G(d,p) basis set. The GQDs and the TMA structures were first optimized, and Fukui functions were calculated to support the choices of adsorptions sites. The potential energy curves (PECs) of the adsorption process were obtained based on a rigid scan calculation. Based on the well depth of the PECs, the most stable complex was formed between the TMA molecule and the edge hydroxyl of the GQDs-OH, while the less stable, was formed with the GQDs-COOH sites. To confirm the DFT predictions, gas sensing measurements were performed at room temperature by exposing the GQDs to a variable TMA concentration. The GQDs-OH sensor showed an enhanced response with sensitivity four and three times higher than the GQDs-Ep and GQDs-COOH, respectively, which is in agreement with the theoretical results. To verify the application of these sensors, GQDs-OH sensor was used to monitor the freshness of shrimp, and satisfactory results were achieved. Besides, the obtained insights can in principle be explored to develop other GQDs-based gas sensors.

Semi-covalent imprinted polymer employed for preconcentration and determination of tetracycline in milk samples with amperometric detection in a BIA system.

Letícia Maria Effting[1], Luana Rianne da Rocha[2], César Ricardo Teixeira Tarley[2]

[1]Universidade Estadual de Londrina (*Química*) , [2]Universidade Estadual de Londrina

e-mail: leticia.effting21@uel.br

An interesting method of sample preparation is the molecularly imprinted solid phase extraction due to the selective adsorption of polymer for the target analyte. Thus, in the present work, an analytical method was developed based on the off-line preconcentration of tetracycline (TC) using a molecularly imprinted polymer and amperometric determination in batch injection analysis system using a modified screen-printed carbon electrode with AuNPs. A new tetracycline-imprinted polymer was synthesized using a semi-covalent method. In this synthesis, the template-monomer complex was synthesized by the reactionof 3-isopropenyl-α,α-dimethylbenzyl isocyanate (IPDMBI) with TC. The removal of the template by a simple thermal reaction produced specific tetracycline recognition sites. Thenon-imprinted polymer (NIP) was synthesized the same way, without the presence of thetemplate. Based on the relative selectivity coefficients, the MIP showed higher selectivity towards TC in relation to NIP, even having a smaller specific area (183.21 m2 g-1) than theNIP (206.12 m2 g-1), indicating that the greatest adsorption capacity of TC by MIP is due toimprinted effect created during synthesis. Based on the obtained results in adsorption kinetics study, the percent removal increased with time, reaching binding equilibrium in 15min for both polymers. Moreover, adsorption isotherms showed TC-rebinding capacity of
76.74 mg g-1 for IPDMBI-MIP. The method analytical presented limit of detection and quantification of 0.003 and 0.011 μmol L-1, respectively, and preconcentration factor of 214.83-fold. The applicability of the method was demonstrated by performing analysis of TC and other compounds of the family, in different milk samples, with recoveries being between 93.0-102.0%.

SERS sensing of corrosion inhibitors using Ag nanoparticles immobilized on cellulosic supports

Paulo Henrique de Melo Toledo[1], Eduardo Ariel Ponzio[2], Gustavo Fernandes Souza Andrade[1]

[1]Universidade Federal de Juiz de Fora (*Química*) , [2]Universidade Federal Fluminense

e-mail: ptoledo@ice.ufjf.br

One of the most used methods for mitigating and controlling corrosive processes that lead to decreased flow in pipes is the use of corrosion inhibitors [1]. Both corrosion and incrustation inhibitors can be found in the water produced in oil extraction, which is a by-product of oil exploration, having a very complex matrix with the presence of numerous organic and inorganic substances, which can be very harmful to the environment. SERS spectroscopy has great potential for the analysis of corrosion inhibitors due to the great sensitivity of the technique for monitoring analytes at low concentrations, providing vibrational information of the analyzed molecules [2]. Flexible substrates constructed by immobilizing silver nanoparticles (AgNP) on paper proved to be very promising for the application of the SERS technique in complex systems. The purpose of the present work was to use paper support (cellulose) covered by a range of AgNP to build high-performance SERS substrates and to test the detection of the corrosion inhibitor benzotriazole (BZT). It was found that the power density of the laser used (λ_0= 632,8 nm) should be as low as possible to avoid degradation of the analyte. Using a nominal power of 5 mW in a Bruker Senterra spectrometer, it was possible to obtain spectra of this corrosion inhibitor with a high S/N ratio for BZT concentrations as low as $1,0\times10^{-7}$mol L^{-1}. The SERS spectra obtained are similar to those previously reported in the literature. The results indicate that it is possible to obtain SERS spectra at very low concentrations of this inhibitor on AgNP/paper substrates, which indicates the possibility of using it for more complex solutions.

Magnetoelastic sensors are transducers with a working principle based on the resonance phenomenon. They are potential devices for application as biosensors in health-related areas as they respond to surface mass variations with high sensitivity. For diagnostic purposes, they are a good alternative once biological interactions cause mass increase, allowing monitoring physico-chemical parameters. However, it is necessary to functionalizethe sensor surface to promote the detection of the desired pathogen. Furthermore, whenused for detection of viral particles, it is necessary to use gold nanoparticles (AuNPs) to amplify the response signal. In this context, the objective of this work was to functionalize the surface of magnetoelastic sensors and AuNPs for application in Sars-CoV-2 diagnosis. For this, the biosensors were obtained by building biological layers of 11-mercapundecanoicacid (11-MUA) and antibodies on the sensor surface. The ATR-FTIR technique was used for characterization. AuNPs were functionalized by physical adsorption. The resonance frequency response of test (with recombinant protein for Sars-CoV-2) and control biosensors was read on a network analyzer. The ART-FTIR results confirmed the presence of 11-MUA and antibodies on the surface of the biosensors. Regarding the resonance frequency shift response, the control biosensors (in the absence of the recombinant protein) exhibited a frequency shift of approximately -40 Hz. As for the test biosensors, which were placed in contact with the recombinant protein, the frequency shift was approximately -160 Hz. The presence of AuNPs on the surface of the test biosensors was also confirmed by SEM/FEG images.

Synthesis and characterization of molybdenum-based material for the construction of sensor devices for diabetes biomarkers

Douglas Scarabello[1], Marcelo Ornaghi Orlandi[1], Rafael Aparecido da Silva[2]

[1]Universidade Estadual Paulista / Instituto de Química (*Departamento de Engenharia, Física e Matemática*) , [2]Universidade Estadual Paulista (*Departamento de Física*)

e-mail: douglas.scarabello@unesp.br

Volatile organic compounds (VOCs) can be considered non-invasive biomarkers due to the correlation that has been shown between certain VOCs and specific types of diseases through conventional breath analysis [1]. Acetone, for example, has been found to have a direct correlation with Diabetes Mellitus by analyzing its concentration in breath samples [2]. Currently, diabetes monitoring is carried out using glucose meters, which can be intrusive, painful and inconvenient [2]. Therefore, the focus of this work is to synthesize a chemical compound that is sensitive to the presence of acetone, in order to reduce the damage caused by conventional analysis methods. The material used for this purpose is based on molybdenum oxide, produced using the hydrothermal method, modified with yttrium oxide, which was added to the base material through coprecipitation. Synthesized compounds and its precursor were characterized using X-ray diffraction, transmission electron microscopy (TEM), and scanning electron microscopy (SEM) techniques. The response of the samples in the presence of acetone was monitored to verify the potential of the material for use in biomarker sensors. SEM showed that the insertion of yttrium oxide caused significant changes in the microscopic structure of the base material. Moreover, the decoration of molybdenum oxide resulted in changes in the response parameters during the analysis of electric current in the presence of acetone. Thus, this work demonstrated that the presence of yttrium oxide in molybdenum oxide causes structural changes and changes in the electric responses of the base material.

Humidity control is crucial for product quality and safety. For example, high humidity can spoil food and pharmaceuticals, and damage electronic devices. Reliable and accurate humidity sensors are essential to maintain product quality. In this study, a graphene oxide-silver nanowire hybrid film was synthed and evaluated as a highly sensitive humidity sensor. Graphene oxide (GO) has excellent water adsorption due to oxygenated functional groups like carbonyl, carboxyl, hydroxyl, and epoxy. Among these functional groups, hydroxyl groups (OH) have the highest potential to interact with water molecules, making GO anexcellent material for humidity sensors [1]. Silver nanowires (AgNWs) [2] and reducedhydroxyl-rich graphene oxide (rHGO) were synthed and characterized using modified polyol and Hummers methods. Humidity sensors were created by drop-casting onto interdigitated aluminum electrodes (IDE). Two types of IDE were fabricated: one with HGO only, and the second with HGO blended with silver nanowires to improve conductivity without affecting HGO's adsorption capability. The sensors were tested by placing and sealing them in pots with varying humidity levels (14% RH to 96% RH). The behavior of electric current, resistance, and impedance in response to humidity variation was observed. The sensors exhibited high sensitivity, fast response and recovery times, low hysteresis, and were compatible with real-time humidity control, such as monitoring human breathing.

SYNTHESIS OF CERIUM OXIDE NANOPARTICLES OBTAINED BY MICROWAVE-ASSISTED HYDROTHERMAL METHOD

Murillo Donizeti dos Santos Rosa[1], José Fernando Queiruga Rey[1], Marcia Tsuyama Escote[1]

[1]Universidade Federal do ABC

e-mail: murillo.donizeti@ufabc.edu.br

In recent years, the search for increasing the surface-to-volume ratio of nanoparticles has demanded great efforts from the scientific community in order to understand the physicochemical properties of new nanomaterials. Increasingly, nanoparticles are developed with sophisticated molecular control in order to satisfy a wide variety of applications in various fields of science. Among the different types of materials existing in the field of nanotechnology, cerium oxide nanoparticles (NPs, nanoceria) have stood out as a promising substance in various scientific approaches, such as catalysis and biomedicine, due to its intrinsic properties, being: high thermal and chemical stability, biocompatibility and, mainly, the ability to release and store oxygen in its structure. The present study has the main objective of producing cerium (III) oxide nanoparticles, employing the microwave-assisted hydrothermal synthetic route, using aqueous cerium nitrate hexahydrate [$Ce(NO3)3.\ 6H2O$, 0.05 M] as precursor solution and potassium hydroxide (KOH, 1.2 to 6 M) as a mineralizing agent, under different radiation times at 180°C and without the addition of surfactants. The structural, morphological, and optical properties of the NPs willbe characterized by Raman spectroscopy, low-angle X-ray scattering, X-ray diffraction, field emission scanning electron microscopy (SEM-FEG), and spectroscopy in the UV-vis region, respectively. Raman spectra and XRD patterns indicate the formation of fluorite-like crystalline structures belonging to the Fm3m space group in all samples. Furthermore, it was observed that the microwave exposure time and the concentration of the mineralizing agent have a direct influence on the morphology and crystallinity of the nanostructures. By analyzing UV-vis spectroscopy measurements, maximum absorption peaks were observed between 321.29 and 335.58 nm and bandgap between 2.87 and 3.44 eV.

Synthesis of Fe2O3 nanoparticles supported on carbon nanotubes for electrochemical detection of 17-β-estradiol

Mayara da Silva Araujo[1], Juliana Costa Rolim Galvão[1], Vanildo Souza Leão Neto[1], Roberto Matos[1], Luiz Henrique Dall Antonia[1], Roberta Antigo Medeiros[1]

[1]Universidade Estadual de Londrina (*Química*)

e-mail: asmayara@uel.br

The magnetite (Fe_2O_3) and the carbon nanotubes (NTCs) are materials with excellent electrocatalytic activity, which can greatly enhance the electron transfer velocity in electrochemical sensors. [1]. This work reports the synthesis of Fe_20_3nanoparticles supported on the CNTs surface (Fe_20_3-NTCs), and their application in the construction of an electrochemical sensor for determination of 17-β-estradiol (E2). The Fe_20_3-CNTs were synthed using a hydrothermal method, where a mixture of Fe_2O_3, CNTs, $NaNO_3$, and polyvinylpyrrolidone in ultrapure water was heated at 160°C for 12 hours in an autoclave. The resulting precipitate was filtered, dried, and calcined at 600°C for 3 hours. The electrochemical sensor was constructed using an aqueous dispersion of Fe_20_3-CNTs and dihexadecylhydrogenphosphate, both in concentration 1,0 mg mL^{-1}. Then, 6.0 μL of the dispersion was dropped onto the surface of a glassy carbon electrode (GCE) and dried at room temperature for 2 hours. The Raman spectra of the Fe_20_3-CNTs, showed bands at 226 cm^{-1}(vibration mode A_{1g}), at 290 $cm^{-1}$and 406 cm^{-1}(both associated with the vibration mode $E_g$of Fe_2O_3). The energy dispersive spectra of Fe_2O_3–CNTs indicates the presence of carbon, iron and oxigen elements as expected. In the cyclic voltammograms obtained using a Fe_2O_3-NTCs/GCE is showed only a peak current, for E2, at 0,8 V vs Ag/AgCl (3,0 mol L^{-1}KCl), the current peak intensity was 1,9 times higher when compared to current response obtained with bare GCE . The electroanalytical method developed presented a good sensitivity and samples analyzed of pharmaceutical formulations, synthetic urine and lake water were analyzed.

e-mail: drleandrosrr@gmail.com

SnO and SnO2 oxides are wide band gap oxide semiconductors with Sn+2 and Sn+4 chemical states, respectively. The first is an intrinsically p-type material while the second is n-type [1]. SnO2 is one of the most common inorganic material used in chemical sensing, especially for carbon monoxide detection. However, in the recent years, SnO has received much attention because it shows great promise as an alternative to SnO2 for use in high performance gas sensor devices [2]. The main objective of this work is the synthesis, morphological and structural characterization, and electrical evaluation of tin(II) oxide undoped and Ni-doped micro-plates for CO sensing applications. The undoped and doped (1% and 2% of Ni) tin oxide compounds were synthesized by the microwave assisted hydrothermal (MAH) method, under a reductive atmosphere. The samples were characterized using XRD, Raman spectroscopy, SEM and UV-Visible spectrophotometry. For the gas-sensing measurements, an alumina wafer was used as a substrate, with an adhesion layer of titanium and a thick platinum film used as the electrode. Films were prepared on top of the resulting substrate by a screen-printing-like method. The measurements were made in an optoelectronic device for the characterization of semiconductor materials under temperature and pressure control. The MAH method has proven to be versatile, and constitutes a viable methodology for the synthesis of SnO micro-plates under reductive atmosphere. Samples showed high chemical stability up to 400°Cand the incorporation of Ni improved sensor operation temperature. Ni-doped samples showed high conductivity at air and CO at ambient pressure, and catalized the reaction withCO, which demonstrated the potential of Ni-SnO as sensors for the detection of CO.

Synthesis of zinc tin oxide structures applied for gas sensors

Ranilson Angelo da Silva[1], Mateus Gallucci Masteghin[2], Marcelo Ornaghi Orlandi[1] [1]São Paulo State University (*Engineering, Physics and Mathematics*) , [2]University of Surrey (*Advanced Technology Institute*)

e-mail: ranilson.angelo@unesp.br

Semiconductor metal oxide materials, with ternary or quaternary type structures, have been highlighted in the scientific community due to the range of properties resulting from the type of structural alignment of the constituent elements [1,2]. This work reports the growth mechanism of zinc tin oxide-based structures synthesized by microwave-assisted hydrothermal methods and gas sensing performance for nitrogen dioxide (NO_2), hydrogen (H_2), and carbon monoxide (CO) gases. The as-synthesized materials were characterized by X-ray diffraction (XRD), scanning and transmission electron microscopy (SEM and TEM), and nitrogen adsorption/desorption experiments. Cuboctahedron-like $ZnSn(OH)_6$, "thorn-tube-like" $ZnSn(OH)_6/ZnSnO_3$, and "cactus-like" Zn_2SnO_4/SnO_2 structures were obtained by varying the synthesis time of 4h, 12h, and 24h, respectively. Gas sensor measurements showed that $ZnSnO_3$ presents an outstanding lower detection limit to NO_2, in which a 12-fold increase in electrical resistance is estimated in the presence of 1 ppb NO_2 at an operating temperature of 150 °C. Moreover, the Zn_2SnO_4/SnO_2 heterostructure exhibited superior selectivity to NO_2 relative to H_2 and CO, exhibiting a sensor response ~1500 times higher for the oxidizing gas. Hence, it is demonstrated that nanostructures growth engineering can realize ultra-selective and high-performance gas sensor devices through a greater surface area or enhanced contact potential barriers.

Quinolones are a class of heterocyclic organic compounds known for their classical antibacterial clinical use and other diverse biological activities. There has been an increasing interest in the use of quinolone derivatives as ligands for the construction of metal-organic frameworks (MOF) due to their unique, easily functionalized structure with agreat potential for diverse applications. In this work, a new organic ligand precursor, 1-ethyl-4-oxo-1,4-dihydroquinoline-3,6-dicarboxylic acid (IMP10), was synthesized, startingwith the condensation reaction between 4-aminobenzoic acid and ethyl ethoxymethylene malonate followed by a thermal cyclization. The intermediate obtained was submitted to anN-alkylation reaction [1] followed by alkaline hydrolysis, yielding IMP10, in its pure form. The quinolone-Zn-MOFs were initially synthesized from conditions already reported in theliterature for different systems [2]. The synthesis was accomplished by addingZn(AcO)2.2H2O into the IMP10 at ambient temperature. The reagents were dissolved in DMF and NaOH was added as a modulator. The system was incubated at 130 °C for 24 and72 h. After cooling, the separated solids were washed with DMF and EtOH, collected bycentrifugation, and dried overnight at 110 °C. The materials were labeled by their synthesisconditions: MOF-A = w/o NaOH - 24 h, MOF-B = w/o NaOH - 72 h, MOF-C = w/ NaOH - 24h, MOF-D - w/ NaOH - 72 h. The evaluation of structural parameters of these different MOFs was made by X-RD, FTIR and SEM. For further studies, the newly synthesized MOFsare going to be evaluated for the adsorption of organic pollutants in contaminated water [3].

e-mail: carlos.constantino@unesp.br

The wide use of pesticides in the scale agriculture requires the development of strategies to monitor their applications due to the great risk that they represent for the human health. The Raman spectroscopy is a vibrational technique characterized by the inelastic scattering of the light. When the target molecule is close to certain metallic surfaces, such as nanoparticles, the Raman signal can be enhanced up to 10^{10}, leading to the called surface-enhanced Raman scattering (SERS). Therefore, considering its sensitivity and selectivity (vibrational spectrum), SERS is a suitable tool for analyte detection. However, the SERS signal intensity is highly dependent on nanoparticle metal, , shape, and aggregation level, which makes its analytical application routinely a challenge for the field. Here, we have exploit two aspects of the SERS effect when applied in the detection of both pesticides thiram and thiabendazole: the effect of the pesticides on the aggregation of Ag colloids applied as SERS substrates, including the adsorption mechanism, and quantitative analysis. SERS intensity varies linearly from $1.0x10^{-8}$to $4.0x10^{-7}$mol/L with thiram concentration, leading to a limit of detection of $1.7x10^{-9}$mol/L. The loss of linearity (above 10^{-6}mol/L) was associated with changes in the Ag colloid aggregation (and morphology) due to strong interaction between the Ag nanostructures and thiram, leading to S-S cleavage with thiram adsorbing onto Ag surface through S atoms and methyl groups. In the case of thiabendazole, a linear regimen for SERS intensity was found between $1.6x10^{-7}$and $8.0x10^{-8}$mol/L, leadingto a limit of detection of ca. $7.0x10^{-8}$mol/L. Besides, the preferential TBZ adsorption mechanism onto the Ag surface was established by S atoms, leading to a sigmoidal adsorption isotherm, revealing intermolecular thiabendazole interactions and formation of Ag aggregates with distinct morphologies.

In this research, we have synthed carbon dots (CDs) co-doped with nitrogen and sulfur by facile hydrothermal method, using citric acid and cysteine as carbon source. The effect of solid-state thermic treatment (STT) at 303-453 K on the , surface, fluorescence and cellular cytotoxicity of the CDs were

systematically investigated [1, 2]. Through a simple STT, it was possible to tune surface states and the average of the CDs, causing a permanent red shift. Initially, CDs showed a decrease in cell viability with increasing concentration. However, after STT, its viability remained constant with an increase in concentration. Here, we show the possibility to label the cells cytoplasm according to the CDs fluorescence emission before (blue emission) and after STT (red emission). The CDs studied in this paper show selective luminescence properties, which are fundamental for any cell imaging application [3].

Electrochemistry and sustainable platforms like paper and bacterial cellulose offer portable, affordable, and user-friendly devices. However, current methods for creating electrochemical paper-based analytical devices (ePADs) can be cumbersome, poorly reproducible, and challenging to scale. We present a new simple, versatile, single-step technique for creating laser-induced graphene on bacterial cellulose surfaces, eliminating chemical reagents and controlled condition needs. The production process, including CO2 laser output and substrate functionalization, was optimized, and the resulting graphene was characterized, revealing a highly graphitized, porous material with a large specific surface area. The straightforward laser engraving process facilitated scalable electrode preparation and yielded outstanding reproducibility of potentiometric signals, with low variability between measurements (2.13%) and between devices (1.91%). The low-cost of the materials, the minimal equipment requirements, the single-step protocol, and the produced material's features offer a promising green, portable, and highly reproducible electrode fabrication method.

e-mail: mariahelena1993@gmail.com

Honey is a concentrated solution of sugars, mainly glucose and fructose, produced by bees fromflower nectar or plant-sucking insect secretions. When commercialized, it is of great relevanceto know if the honey is in fact pure or may have suffered some kind of adulteration. Accordingto data from the National Health Surveillance Agency (ANVISA), approximately 30% ofcounterfeit honey is made from sugarcane molasses. This is a by-product of the sugarproduction process, where sugarcane juice is heated and concentrated to obtain crystallizedsugar. The main aspects verified in honey analysis include purity, moisture content, acidity, andsugars. Distinguishing between honey and molasses is a challenge for many people, as thesetwo products are very similar in appearance and taste. In this context, a study was conducted todevelop an electrolyte-gated transistor (EGT) and extract the typical transistors parameters toinvestigate the device capability capable of different honey and molasses. The EGT structure isindium-tin oxide (ITO) interdigitated electrodes as source and drain, poly(3-hexylthiophene-2,5diyl) (P3HT) as channel and a platinum tip for the gate. The electrolyte layer is composed ofa drop of honey or molasses. The theoretical fit was based on OFET model [1]. The used honeyis from Jataí bees ***(Tetragonisca angustula),***a stingless bee native from Brazil commonlyknown as Jataí. The extracted parameters to compare honey or molasses in the EGT were fieldeffect mobility, transconductance, on/off ratio, and threshold voltage. Preliminary resultsshowed that it is possible to differentiate honey from molasses as electrolyte in the EGT byanalyzing the parameters of the transistors.

e-mail: william.martini@unifesp.br

Silver nanoparticles (AgNP) are widely used in environmental applications, including the treatment and monitoring of water quality. Furthermore, their favorable photophysics allows AgNP application as a sensor for the detection of different organic molecules in aqueous media through the Surface-enhanced Raman Spectroscopy (SERS) technique [1]. Therefore, the use of Raman spectroscopy combined with the properties of metallic nanoparticles, such as silver, has enabled the identification of pollutants in water, soil, and food [2]. In this scenario, we propose here the engineering of thin films composed of silver nanoparticles of different morphologies (sphere and prism) deposited onto glass slides by the blade coating method to detect the organic pollutant molecules Atrazine (pesticide), Ibuprofen (drug), and Methyl Orange (dye). UV-VIS spectra, dynamic light scattering (DLS) measurements, atomic force microscopy, and scanning electron microscopy confirmed the morphologies and of AgNP and the functionalization of the surface of the blades. The pollutant models were detected at very low concentrations (10^{-4}~10^{-6}M) in an aqueous solution by Raman spectroscopy and SERS effect due to AgNP deposition and plasmon effect. In addition, the photodegradation of these molecules was followed through the SERS effect, in which it was possible to observe changes in their spectral profile as the photobleaching occurred. These promising results augur well for further developments of AgNP plasmonic thin films for pollutants photodegradation products detection.

e-mail: fechine@ufc.br

A sensor device utilizing doped-carbon quantum dots is proposed in this study for detecting nitrite in meat products through fluorescence quenching. To create the sensing platform, boron-doped carbon quantum dots functionalized with nitrogen (B,N-Cdot) were synthed through a one-step hydrothermal process using citric acid, boric acid, and branched polyethyleneimine as sources of carbon, boron, and nitrogen, respectively, resulting in an impressive quantum yield of 44.3%. Following an investigation into their chemical structure and fluorescent properties, the B,N-Cdot in aqueous suspensions exhibited high selectivity for NO_2^- in a linear range of 20 to 50 mmol L-1 under optimal conditions at a pH of 7.4 and a 340 nm excitation wavelength. Additionally, the prepared B,N-Cdots successfully detected NO_2^- in a real meat sample with a recovery rate ranging from 91.4 to 104% within the analyzed range. Consequently, a B,N-Cdot/PVA nanocomposite film was produced, which emits a blue light under excitation at 360 nm, and a preliminary detection of NO_2^- in meat products was conducted using a smartphone application. The newly developed sensing device, featuring a highly fluorescent probe, has the potential to aid in the development of a fast and cost-effective strategy for detecting NO_2^-.

UV light-assisted ozone gas sensors based on $W_{1-x}Mn_xO_3$ nanostructures

João Victor Nascimento de Palma[1], Maria Inês Basso Bernardi[2], Waldir Avansi Junior[1], Luís Fernando da Silva[1]

e-mail: jvnpalma@gmail.com

The nanostructured $WO_3$is a metal semiconducting oxide (MOX) that has been widely used as resistive gas sensors for the detection of noxious species[1]. The photoactivation of these gas sensors is a way for its operation at room temperature of such sensor devices[1,2]. Herein, we present an investigation of the influence of annealing temperature and Mn concentration on the microstructural and surface properties of nanostructured WO_3prepared by the polymeric precursor method, in addition to the effect of Mn content on the photoactivation of the samples. X-ray diffraction analyses revealed the monoclinic structure for the $W_{1-x}Mn_xO_3$samples with an increase of crystallization degree with annealing temperature and Mn content. Scanning electron microscopy images showed that $W_{1-x}Mn_xO_3$crystals exhibit nanometric particle size. X-ray photoelectron spectroscopy analysis revealed that Mn^{+2}ions occupied the W^{+6}sites. Electrical measurements revealed that the samples were sensitive to UV and violet light stimulation. Regarding the sensing performance, experiments performed exposing the samples to different ozone (O_3) levels under UV light stimulation at room temperature, revealed that the $W_{1-x}Mn_xO_3$samples detected sub-ppb O_3levels.

The detection of toxic gases is becoming increasingly important for human and environmental safety, in modern society, gases produced by fossil fuels consumption and extraction, automobiles, and factories need to be monitored to guarantee safe levels of exposure and decrease the risk of accidents [1]. Metallic oxide semiconductors (MOS) have been extensively studied for gas sensing applications since they present excellent sensitivity and response to several different gases, in addition to having excellent thermal and chemical stability and a low cost of production [1]. However, MOS exhibit a high operatingtemperature, which renders them unusable for the detection of flammable gases, and lowselectivity when exposed to more than one gas simultaneously [1]. Among metallic oxides, ZnO presents the characteristics for gas sensing and has been broadly studied, obtainable indifferent morphologies using low-cost synthesis methods [2]. In this study, ZnO was synthesized via controlled precipitation in two different morphologies named "needles" and"donuts" and after morphological and structural characterization the material was tested asa gas sensor for O_3, NO_2, CO, and acetone at different concentrations and operation temperatures to analyze the effects of morphology in the sensing properties. The sample inthe form of needles presented the best result about the detection of ozone gas while the sample in the form of donuts presented the best result concerning CO and NO_2 gases.

Medical devices, such as catheters and orthopedic implants, play a crucial role in patient care. However, they can be associated with the insurgence of healthcare-associated infections (HAIs). The use of coating to prevent HAIs on medical devices is of major importance [1,2]. Recently, chitosan-based films crosslinked with tannic acid, $FeSO4$ and loaded with gentamicin [1] have shown promising antibacterial results activity for over a month. To extend the performances of this system, we investigated the impact of different antibiotics on their release kinetics and their antibacterial activity. Antibiotics with diverse chemical properties, namely, gentamicin, linezolid, trimethoprim and moxifloxacin were selected for this study. Films were synthetized with chitosan, tannic acid 20%, $FeSO4$ 5% and antibiotics 5%, then characterized in terms of thickness, which varies between 16 to 28 μm; mass loss, ranging from 15 to 30 %; and swelling, with values around 200% for all tested conditions. The antibiotics linezolid and moxifloxacin presented the highest difference in their release kinetics profiles in PBS. While linezolid was released in only three days, moxifloxacin was released over a period of 70 days with the smallest burst release. The results for the antibacterial activity corroborated the release profiles of the antibiotics over time. In conclusion, our research shows that the selection of the antibiotic significantly impacts the release kinetics from fast-acting to prolonged release. This provides valuable insights in terms of drug matrix interaction, and allows an appropriate choice of formulation for film coatings to prevent HAIs in medical implants.

e-mail: quimica.lucasbahianogueira@gmail.com

The organization of the bone tissue can be investigated from a physical, chemical, and biological point of view1. In a very simplified description, osteoblasts secrete an extracellular matrix composed mainly by type 1- collagen, in which minerals are deposited following kinetic and thermodynamic parameters. Moreover, osteoblasts also release extracellular vesicles able to regulate the concentration of phosphate and pyrophosphate (mineralization inhibitor), allowing mineralization of the extracellular matrix2. This highly controlled process can be studied in detail using biomimetic models composed by phospholipids able to reproduce in part the structure of osteoblasts′ cell membrane, collagen, and hydroxyapatite. Choosing the suitable molecules and structures to simulate the bone matrix in a reliable way is challenging. In this presentation, we will describe biomimetic models based on Langmuir films and 3D scaffolds in an attempted to reproduce the bone extracellular matrix. Lipidomics and proteomics analysis of extracellular vesicles released by osteoblast supported the choice of cholesterol, phosphatidylserine, and phosphatidylcholine and the main lipids and alkaline phosphatase and orphan phosphatase 1 as the main enzymes participating on this process. Collagen was chosen due to its abundance in the extracellular matrix. Polysaccharides were also added to the models in order to fulfil the role of non-collagenic molecules. Hydroxyapatite was chosen as a mineral model for the production of the mineralized matrices. These biomimetic models were used to study cell events related to bone mineralization and were also useful for the development of biomaterials based on surface modification of implants and membranes potentially appliable for bone replacement. e-mail: paulo.lisboa@unesp.br

Yttria-stabilized Polycrystalline Tetragonal Zirconia (Y-TZP) is a material with great potential for dental and medical applications due to its mechanical properties, especially its fracture toughness, however, it is prone to low-temperature degradation (LTD), which compromises its performance and survival probability. Nanometric Y-TZP with non-homogeneous yttria distribution has been shown to present improved hydrothermal degradation resistance and mechanical properties, i.e. higher fracture toughness and characteristic strength [1]. In this work, step stress accelerated life testing and the mechanical characterization of fatigued samples (mechanical cycling) were performed in a wet environment to determine a more realistic probability of survival of nanostructured Y-TZP materials with non-homogeneous yttria content. Physical (Relative density), structural (XRD and Raman Spectroscopy), microstructural (SEM and AFM), and mechanical characterizations (Accelerated fatigue testing, Biaxial flexural strength test, and Vickers hardness test) of nanostructured and conventional Y-TZP were evaluated and compared. Nanostructured Y-TZP materials with non-homogeneous yttria presented higher reliability after 50000 cycles at 800 MPa than conventional Y-TZP (83% vs. 6%) and higher characteristic strength and Weibull modulus after 2x106 cycles of 110 MPa with a frequency of 15 Hz (1419 MPa and 14.3 vs. 1157 MPa and 10.6).

Nanostructures For Probing And Transfecting LivingCells

Christelle Prinz[1]

[1]Lund University / Lunds universitet (*Physics*)

e-mail: christelle.prinz@ftf.lth.se

Interacting with cells in a minimally invasive manner is key to performing longitudinal studies in biomedicine. One example where minimally invasive interaction with cells is important is when injecting material inside cells, either to probe cells, or to change the cell phenotype (transfection). Current delivery methods such as viral vectors electroporation and liposome delivery (lipofection) have many drawbacks. Viruses suffer from being costly, can be unsafe due to insertional mutagenesis, and are limited in cargo . Electroporation and lipofection, suffer from low cell viability and efficiency. To address this issues, nanostraws can be used to deliver cargos inside cells. Here, a review of our work using nanowires and nanostraws for developing cell transfection tools will be presented. For instance, we have used nanostraws to inject nanodiamonds in living cells. A long-standing question in the field concerns the state of the cell membrane on such hollow nanostructures. In order to investigate the state of the cell membrane during and after transfection, we have performed video-rate live cell STED microscopy imaging of the cell membrane when interfaced with nanostraws. The time-lapse STED images reveal that the cell membrane opens entirely on top of nanostraws upon application of gentle electrical pulses, and that it recovers and seals 30-60 min after turning off the electrical field. We further demonstrate that we can achieve direct delivery of fluorescent nanodiamonds to the cytosol using nanostraws. The nanostraw delivery leads to efficient and rapid nanodiamond transport into cells compared to when incubating cells in nanodiamond-containing medium. Moreover, whereas all internalized nanodiamonds delivered by incubation end-up in lysosomes, a significant larger proportion of nanostraw-injected nanodiamonds are located in the cytosol, which opens up for using nanodiamonds as cellular probes.

Treatment of titanium by electrolytic plasma, aiming application in dental implants with drug delivery system

e-mail: nataliazpm@hotmail.com

Pores with controlled number, size, and distribution are of fundamental importance in drug delivery systems. In dental implants, for example, they additionally need to have adequate wettability, chemical composition and biocompatibility. In the present work, titanium was oxidized by pulsed plasma electrolytic (PPEO), using 0.025 M sodium dihydrogen phosphate and 0.25 M calcium acetate as electrolyte. The samples were treated for 2 min or 6 min, using pulses of 50/100 and 100/50 (time on/off time - Ton/Toff) with a current density of 38 mA/cm2. These pulse times are shorter than those usually used in the literature. After treatment, wettability, Ca/P ratio, number, and pore distribution were evaluated. Cell adhesion/proliferation was also evaluated. It was observed that smaller and more uniform pores are obtained in smaller Ton and/or treatment time. Thus, under PPEO with pulse times close to the plasma discharge times conditions, were the most appropriate for use in implants with drug delivery systems.

The 3D printing of ceramic scaffolds for bone regeneration allows for the creation of standardized structures with complex geometries and controlled porosity, making the method highly reproducible. Incorporating wollastonite, a bioactive ceramic, has shown positive results in bone formation, with low toxicity and efficient bone integration in the scaffolds. The alpha phase of wollastonite is highlighted for its thermal and mechanical stability, being more stable at lower temperatures, below 1120°C, and constituting a monoclinic structure. Additionally, wollastonite exhibits high reactivity and adequate biocompatibility, making it a promising material for applications in bone tissue engineering. The process of scaffold formation involved tests of precursor powder granulometry, alpha phase wollastonite, to determine particle size and analysis of density by helium pycnometer. 3D printing of alpha-phase wollastonite scaffolds was performed using a paste/bioink containing the precursor material and the binding agent PEG 400, to improve the mechanical properties of the scaffolds. Printing was carried out using a paste extrusion printer, followed by the sintering process and characterization of the scaffolds. Characterizations by X-ray diffraction (XRD), Raman spectroscopy, scanning electron microscopy (SEM), and rheology revealed that the scaffolds exhibited appropriate porosity and well-defined crystalline phases. As a result, the findings demonstrated that the use of ceramic scaffolds based on alpha-phase wollastonite is a promising option for biomedical applications due to their suitable mechanical and structural behavior.

Additive manufacturing of bioinspired and functionalized microneedles with active-passive hierarchical structures for self-decontaminating action

Alisson Silva de Albuquerque[1], Karina Maria de Souza Silva[1], Janaína Versiani dos Anjos[1], Petrus Santa-Cruz[1]

[1]Universidade Federal de Pernambuco (*Departamento de Química Fundamental*)

e-mail: alisson.albuquerque@ufpe.br

This work aims to produce with active materials, printable microneedles inspired by the microstructures of the stinging hairs of *Urtica dioica* (L.). To achieve this, a printable and biocompatible polymeric nanocomposite is being developed, featuring self-decontaminating action on printed surfaces. The nanometric phase of this composite was formed by silver nanoparticles reduced in a printable resin by photoreduction, aiming to confer bactericidal properties to the material [1]. Multi-walled carbon nanotubes (MWCNT) constitute another nanometric phase of the composite, used for the formation of oriented nanoneedles by applying an electric field (DC) during printing [2] to achieve self-decontaminating action against viruses on the printed surfaces [3]. MWCNT in resin was aligned by applying a constant electric field. A biocompatible resin was developed in collaboration with the Laboratory of Organic and Medicinal Synthesis (LASOM/UFPE) and used as the polymer phase of the nanocomposites in the printing of bioinspired microneedles. Cytotoxicity tests were conducted on the synthesized resins, with and without the prepared nanomaterials, in collaboration with FIOCRUZ/PE (Aggeu Magalhães Institute), which indicated the samples that had cellular viability. The printed bio-inspired microneedles were characterized by optical microscopy, which indicated that their shapes and dimensions were preserved from the model with little deviation, and their surfaces were analyzed through AFM and SEM. The synthesized resins are being characterized by FTIR and DSC.

Acknowledgments

Abstract: The luminescent metal-organic framework (LMOF) [$Eu_2(BDC)_3(H_2O)_2$], entitled EuBDC, has been previously tested as a latent fingerprint developer, on porous, nonporous, and multicolored surfaces obtaining sharp images for comparison and identification of suspects. Since the EuBDC will be in direct contact with fingerprint experts, it is important to assess its toxicity to ensure safety in its use. Therefore, in this study we focused on the evaluation of the acute oral toxicity and the liver histopathology. The synthesis followed Reineke *et al.*[1] reported method and the material produced showed the same XRD patterns, regular europium transitions, a red-orange color when excited with UV light (254nm), with 77.4% of its particles ranging from 0.1 to 10μm. For the toxicity study, youngWistar rats were evaluated using OECD protocol no. 423. The administrated dose was closeto 2000 mg/kg and the animals were observed closely for the first 4 h, periodically duringthe first 24 h, and daily for 14 days. During this period, the following parameters were evaluated: animal behavior, water and food intake, body weight, organs macroscopic changes and weight (liver, heart, spleen, lung, and kidneys), animal mortality, and liverhistopathology. No signs of changes were observed in animal behavior, nor signs of toxicityin any of cited parameters, and in the liver tissue, when compared to the control group. Additionally, no animals died, which classified the EuBDC in the Globally HarmonizedSystem (GHS) category 5 (the least toxic), with a LD_{50}>5000 mg/kg. Finally, this LMOF canbe safely used as a latent fingerprint developer, although more toxicity studies are requiredfor a wider margin of safety.

It is already known that the relationship between microstructure and macroscopic properties in polymers is a central key to understand and control the desired results when using these materials. Ultra high molecular weight polyethylene (UHMWPE) is a polymer used as a bearing surface in orthopedic implants due to its outstanding physical and mechanical properties. Preferential crystalline orientation in its macromolecular chains can result in anisotropic physical properties. On the other hand, modifications in the structure of the polymer have a direct effect on its wear. It is because this polymer is considered a soft material and its deformation can induce transformation from amorphous phase into crystalline ones with preferred orientation [1]. Fortunately, atomic force microscopy (AFM) shows up as a powerful tool to image molecular structure of polymers. Even though it is a challenge, crystalline molecular structures can be observed with AFM operated in tapping mode [2]. In this context, the goal of this work is to image surfaces of UHMWPE subject to plastic deformation. UHMWPE subject scratch tests, under different scratching patterns, was imaged to identify crystalline orientation in the wear tracks. Besides that, UHMWPE subject to a plane strain compression was also imaged and its directional polymeric chainscould be observed. AFM images helped to understand the behavior of the macromolecularchains under both abrasive and compressive stresses.

Barium Titanate-doped Hydroxyapatite for Bone Tissue Engineering Using Freeze-Casting Process

Alysson Martins Almeida Silva[1]

[1]Universidade de Brasília (*Engenharia Mecânica*)

e-mail: alyssonmartins@unb.br

The present work describes the production of barium titanate modificated hydroxyapatite samples for bone tissue engineering applications using the freeze-casting process. Samples containing 0.25%, 0.50%, 0.75% and 1.00% wt% of barium titanate relative to hydroxyapatite were prepared using ball milling technique followed by freeze-casting and heat treatment. Cylindrical monoliths were evaluated using x-ray diffractometry, Fourier Transform Infrared spectroscopy, scanning electron microscopy and microtomography. Results shows peak-shifting in all difractogram and peak splitting at characteristic peak around 30.7°, as a consequence of barium titanate binding to hydroxyapatite, suggesting that barium atoms in barium titanate molecules interacted with hydroxyapatite crystals viaCa2+ ionic sites. XRD results also shows a very pure barium titanate structure, with littlebarium carbonate formation. FTIR analysis also yields characteristic hydroxyapatite band in560 cm-1, also showing characteristic bands at 478 and 598 cm-1 related to Ti-O and O-Ti-Omodes, suggesting once more barium titanate bonded to hydroxyapatite [1]. Scanning electron microscopy presents the porous structure highlighting its direction of alignment,and also showed lamellae solid structure when using dimetylsulphoxide as a solvent for freeze-casting method at -130 °C. Microtomography suggests that the porous structure wasaligned to heat gradient as expected, and also radial growth was noted to be random, due toheat conduction properties of Technyl® mold, also no sign of agglomeration or deposition ofbarium titanate was found.

Bioprinting of Carboxymethylcellulose-Laponite Hydrogels with Dental Pulp Mesenchymal Stem Cells

INGRI JULIETH MANCILLA CORZO[1], Diego Noé Rodríguez Sánchez[2], Alexandre Leite Rodrigues de Oliveira[2], Marcos Akira dÁvila[1]

[1]Universidade Estadual de Campinas (*Materials and Manufacturing Processes*) , [2]Universidade Estadual de Campinas (*Nerve Regeneration (LRN) - IB/UNICAMP*)

e-mail: injulimaco@gmail.com

In recent years, bioprinting has emerged as a promising technique for creating functional tissues and organs by enabling the precise and controlled deposition of biomaterials and cells [1]. In this study, we investigated the printability and biocompatibility of Carboxymethylcellulose (CMC) and Laponite hydrogels using dental pulp Mesenchymal stem cells (DMSCs) and a Bio X 3D bioprinter.We formulated CMC-Laponite composite hydrogels with varying concentrations of CMC and Laponite to optimize their rheological properties, ensuring excellent printability and structural integrity. The biocompatibility of the composite hydrogels was evaluated by encapsulating DMSCs and assessing cell viability, proliferation, and differentiation potential. Our results demonstrated that the optimized CMC-Laponite hydrogels exhibited good printability, with the bioprinted constructs maintaining their shape fidelity post-printing. Furthermore, encapsulated DMSCs showed high viability and proliferation, indicating the composite hydrogel''s biocompatibility. This study paves the way for developing patient-specific bioprinted constructs that can significantly enhance the outcomes of regenerative therapies.

Chitosan hydrogel containing bioactive glass aiming at3D printing for tissue engineering

Larissa Ribeiro Lourenço[1], Roger Borges[2], Danilo Justino Carastan[3], Monica Beatriz Mathor[4], Juliana Marchi[1]

[1]Universidade Federal do ABC (*CCNH*) , [2]Faculdade Israelita de Ciências da Saúde Albert Einstein (*School of Biomedical Engineering*) , [3]Universidade Federal do ABC (*CECS*) , [4]Instituto de Pesquisas Energéticas e Nucleares (*CETER*)

e-mail: r.larissa@ufabc.edu.br

3D printing is a rising processing technique in tissue engineering due to high reproducibility and the possibility of complex or even patient-specific models. Chitosan is a promising biomaterial for both 3D printing and tissue engineering, because of its biocompatibility, rheological properties, biodegradability, and cost-effectiveness. Bioactive glasses can help the regeneration of different biological tissues and act as reinforcement for chitosan matrix. In this work, chitosan hydrogels were produced with different concentrations of 58S bioactive glass (0.5 up to 5%wt). For the rheological characterization, frequency, and recovery experiments were carried out. Printability and shape fidelity were evaluated during the 3D printing process. Indirect cytotoxicity assay using Balb/c 3T3 cells was performed to evaluate the biological properties of the scaffolds. The presence of the glass maintained the viscosity properties and increased the recovery percentage. All materials formed filaments and allowed printing with suitable form maintenance. Biological experiments showed high cell viability for all 3D scaffolds, even though a reduction was observed for higher glass concentrations. The results indicate that the studied materials are printable and potentially recommended for tissue engineering applications.

e-mail: quimica.lucasbahianogueira@gmail.com

In this study, we used collagen to fabricate mineralized scaffolds mimicking the microenvironment of the native bone. The sulphated polysaccharide κ-carrageenan (κ-Carr), extracted from renewable sources, was added to the scaffolds to fulfil the role of glycosaminoglycans, due to the similarity of their chemical structure, in the organization of the extracellular matrix and cell attachement.[1,2]Ordered matrices were obtained by self-assembling type I collagen molecules in highly aligned fibrils by slow evaporation of acidic solutions at high concentrations.[3]Fibrillogenesis was promoted from exposition in ammoniac vapours for 24 hours. Scanning electron microscopy images showed a surface formed by a dense and uniform network of intertwined fibrils, while from a side view, it was observed collagen fibrils ordered in a parallel alignment, which is characteristic of dense connective tissues. The incorporation of 5 wt.% κ-Carr promoted changes in the surface morphology but, the presence of collagen fibrils was still observable. After 7 days of culture, MC3T3-E1 osteoblasts were viable both in the absence and in the presence of κ-Carr. The presence ofκ-Carr in the collagen scaffolds stimulated the maturation of the cells to a mineralizing phenotype, as suggested by the overexpression of key genes related to bone mineralization, including alkaline phosphatase (Alp), bone sialoprotein (Bsp), osteocalcin (Oc), and osteopontin (Opn), as well as the ability to mineralize the extracellular matrix after 14 and 21 days. The results indicate that these scaffolds can constitute an appropriate model to study the role of the structural organization of bone-mimetic synthetic matrices in cell function. Development of biopolymeric composites containing bioactive glass for periodontitis treatment

Ana Gabrielli Lemos[1], Kelly Roberta Francisco[2], Osvaldo Freitas[3]

[1]Universidade Federal de São Carlos - Campus Sorocaba (*PPGCM*) , [2]Universidade Federal de São Carlos - Campus Araras (*DCNME*) , [3]Universidade de São Paulo

e-mail: ana.gabrielli.lemos@hotmail.com

Dental caries and periodontal disease are considered the most frequent global problems that affect human oral health. However, in cases of periodontitis, the exacerbated immuneand inflammatory response of the organism itself is largely responsible for the destructionof the periodontal ligament and supporting bone. Thus, the therapeutic approach regardingthe minimization of tissue damage, as well as their recovery, can be considered as relevantas combating the disease-causing microorganisms. A promising material for this applicationis bioactive glass (bioaglass), which has been shown to be an excellent osteoinducer and efficient in inhibiting some microorganisms, but it is available in powder form, which can be lost for saliva during application. In order to restore periodontal tissues, the present work developed a film delivery system containing bioactive glass and allowing its prolonged release. Zein, a hydrophobic protein obtained from corn, was selected as the main material for film formation. When bioactive glass meets biological fluids, it forms a layer similar to hydroxyapatite, which is responsible for binding to bone. It also has osteoinductive capacity, soft tissue binding and antibacterial activity due to the high pH resulting from ion release. The results indicate that the matrix obtained is stable, and the precursors showed synergy in film formation. With the incorporation of bioactive glass, the material became even more homogeneous, with a more regular morphology and good adhesion to the mucosa. Release assays indicated that the bioactive glass exhibited ion releasing activity, releasing morethan 50% of all calcium present and therefore was active in the simulated body fluid.

Effect of surface treatment by plasma enhanced chemical vapor deposition on Ti6Al4V to improvements on anticorrosive properties focused on dental application.

Silvia Mesquita Tamborim[1], Anelise Marlene Schmidt[2], Augusto Versteg[3], Vladimir Jesus Trava-Airoldi[4]

[1]Universidade Federal do Rio Grande do Sul (*Físico-Química*) , [2]Fundação Universidade Federal do Pampa (*Departamento de geologia*) , [3]Universidade Federal do Rio Grande do Sul (*Departamento de Físico-Química*) , [4]Instituto Nacional de Pesquisas Espaciais

e-mail: silvia.tamborim@gmail.com

The recent increase of advanced materials and surface treatments to dental applications have motivated the exhaustive research by new materials. The electrochemical impedance spectroscopy technique is extremely useful to show the destabilization mechanism of the protective layer on Ti6Al4V alloys in the presence of a critic concentration of fluoride ions as 1500 mgL^{-1}. In this sense the protective effect of diamond-like carbon layer deposited by plasma enhanced chemical vapor deposition on Ti6Al4V was monitored by this technique. The values related to elements of simulated equivalent circuit shows better resistive properties to Ti6Al4V with the presence of diamond-like carbon layer. Bode diagrams show more than one time constant and reproduce all interlayers in contact with simulated artificial saliva (Mcllvaine buffer pH=5) containing 1500 ppm of fluoride ions. The protective behavior of the layer deposited against corrosion was evidenced by the higher values of the total impedance at lower frequencies and lower capacitance when compared to bare alloy, proving the barrier effect of this layer. The hardness (H= 20.05GPa), elastic modulus (E =172.55GPa) and ratio H/E (0.11) shows values related to high hardness and elastic modulus. The Raman spectra show Diamond e Graphite bands, at around 1377 cm^{-1}e 1557 cm^{-1}, respectively. The relation (ID/IG) at around 0.77 and width of these bands characterize this layer as a-C:H type of diamond-like carbon. It''s possible to conclude that beside these alloys showing excellent corrosion resistance due to $TiO_{(s)}$, $TiO_{2(s)}$and $Ti_2O_{3(s)}$onto alloy surfaces, the diamond-like carbon can protect this material against fluoride ions in this media.

Electrospun PVDF/HAp-β-TCP composites: Synthesis, Characterization and Biocompatibility.

e-mail: adriane.fisica@gmail.com

The development of new materials for tissue engineering and bone regeneration has become an increasingly important research area in recent years. Polyvinylidene fluoride (PVDF) is one of the most explored polymers for biomedical applications owing to its piezoelectric properties of its β phase. However, PVDF only does not meet all requirements, such as biocompatibility, bioactivity, and enhanced mechanical properties. In this context, PVDF has been used in combination with hydroxyapatite (HAp) and beta-tricalcium phosphate (β-TCP) to overcome these requirements. In recent decades, PVDF-based nanofibers have been successfully synthesized, resulting in a large surface contact area, which leads to enhanced properties, mainly targeting tissue engineering. PVDF/HAp-β-TCP composites were synthesized by the incorporation of HAp-β-TCP particles (with different concentrations) into the PVDF matrix solution, followed by electrospinning onto a rotating collector to produce nanofibers. Nanofiber characterizations were performed by various techniques, including X-ray diffraction (XRD), Raman spectroscopy, scanning electron microscopy (SEM) with energy-dispersive X-ray spectroscopy (EDS), mechanical testing, and immersion in simulated body fluid (SBF) for different periods of time. In summary, this study aimed to investigate the synthesis and structural, microstructural, vibrational, and biological characterization of PVDF/HAp-β-TCP nanofibers produced by electrospinning. These results have relevant implications for the development of novel materials for tissue engineering and bone regeneration applications.

Enhancing photodynamic efficiency of gold shell- isolated nanorods (AuSHINRs) upon toluidine blue-o (TBO) conjugation

Alexandre Mendes de Almeida Junior[1], Lucas Gontijo Moreira[1], André Satoshi Ferreira[1],
Sabrina Aléssio Camacho[1,2], Pedro Henrique Benites Aoki[1]

[1]Universidade Estadual Paulista (*Biotecnologia*) , [2]Universidade Estadual Paulista/ Faculdade de Ciências e Letras

Light-based therapies have shown promise in selectively destroying target cells owing to their minimally invasiveness and localized action. Among these therapeutic approaches, photodynamic (PDT) and photothermal (PTT) therapies are notable for their distinct methods of cell inactivation. PDT involves the generation of reactive oxygen species by photosensitizers, while PTT entails the localized increase in temperature induced by photothermal agents. In this work, we shall investigate the synergistic effect of combining both therapies on colorectal tumor cells (CACO2). Thus, photothermal agents based on gold shell-isolated nanorods (AuSHINRs) were conjugated with the photosensitizer toluidine blue-o (TBO), followed by a second coating with silica (AuSHINRs_TBO_SiO2) to prevent leaching. The entire process of synthesis, coating, and conjugation of AuSHINRs_TBO_SiO2 was controlled and characterized with, transmission electron microscopy (TEM), zeta potential UV-vis and fluorescence spectroscopies. The plasma membranes of the target cells were chosen as the primary focus of the photoreactions. Therefore, bioinspired cell membranes based on Langmuir and Langmuir-Schaefer monolayers were chosen to investigate the binding mechanisms and photochemical outcomes at molecular level. Furthermore, the photo-activation of AuSHINRs_TBO_SiO2 in the in vitro culture of CACO2 cells exhibited significantly higher efficiency in reducing cell viability owing to the synergy achieved. Such results demonstrated promising potential in combining both PDT and PTT, and an overview of each step in the study step will be presented herein.

Evaluation of coffee by-products and rosemary extractsas natural preservatives

Luiza Aparecida Luna Silvério[1], Janaína Artem Ataide[1], Érica Mendes dos Santos[1,2], Priscila Gava Mazzola[1]

[1]Universidade Estadual de Campinas (*Faculdade de Ciências Farmacêuticas*) , [2]Katholieke Universiteit Leuven (*Department of Chemical Engineering*)

e-mail: luiza_luna_silverio@hotmail.com

Preservatives are compounds added to drug, cosmetic and food formulations to maintain their physical-chemical and microbiological stability, their efficacy and safety. Synthetic preservatives are linked to adverse effects that led consumers to use those of natural origin [1]. In this study, we used extracts of rosemary leaves and coffee by-products, using ethanol 70% as solvent, to develop a preservative system of natural origin. Coffee extracts showed 43.53 ± 3.49 mg EAG/g of sample and 2.32 ± 0.11 mg EQ/g of sample in the total phenolic tests and flavonoids, respectively, 12.5 mg/mL of minimum inhibitory concentration against Escherichia coli and 25 mg/mL against Staphylococcus aureus and Pseudomonas aeruginosa. The rosemary extract showed 134.59 ± 19.25 mg EAG/g of sample and 1.69 ± 0.13 mg EQ/g of sample in the tests of total phenolics and flavonoids, respectively, 2.5 mg/mL of minimum inhibitory concentration against E. coli, 1.25 mg/mL against P. aeruginosa, 0.3125 mg/mL against S. aureus, and 0.08 mg/mL against Candida albicans. Coffee extracts showed cell viability greater than 79%, not being considered toxic against the human keratinocyte lineage. The combination of extracts showed a partially synergistic action against S. aureus and P. aeruginosa. Thus, the extracts were incorporated into an O/W emulsion, which showed a significant change in consistency, spreadability, cohesiveness and pH parameters, compared to the formulation containing synthetic preservatives, indicating that it is a non-inert preservative system. A challenge test was also performed for the microorganisms S. aureus, E. coli and P. aeruginosa, for which the formulation met the criteria required by ANVISA. In conclusion, the association of coffee and rosemary extracts has potential to develop a new preservative system.

e-mail: guilonghita@gmail.com

Bone resorption is one of the main causes of failure in orthopedic implants. This phenomenon is caused by a mechanical mismatch between the bone and the implant, causing bone resorption and loosening the prosthesis, leading to failure [1].

The use of implants with mechanical properties that mimic those of bone may prevent this type of failure. Additive manufacturing allows the design of implants with custom-designed mechanical properties thanks to its ability to produce porous structures with complex geometries, namely lattice structures. However, these structures have some drawbacks such as their great surface area and the presence of certain zones that may favor the appearance of crevice corrosion [2].

In this work, porous lattice structures and solid bulk samples were fabricated in Ti-6Al-4V using the electron beam melting (PBF-EB) technique. The samples were functionalized using the anodizing technique in an NH_4F + $NH_4H_2PO_4$-containing electrode. The thermodynamic and kinetic parameters of the corrosion process were determined using direct and alternating current electrochemical techniques on the as-fabricated and functionalized samples. The as-fabricated lattice structure samples presented pitting attacks in phosphate buffered saline solution at 37 °C. The functionalization improved the corrosion resistance by hindering pitting attacks on the lattice structures and reducing current density.

e-mail: jogomez.brasil@gmail.com

The biosensor 3D-printed carbon black based on conductive filaments requires functionalization processes and geometry modification to obtain a satisfactory electrochemical response [1]. The surface microstructure of biosensor is important to control both mechanical and physical properties interface [2]. The surface generates chemical residues, and its efficiency depends on the polymeric composition of the filament. Most surface pre-treatments using chemical reagents are expenditure. Laser-Induced Graphene (LIG) activation process emerges as an attractive functionalization method, which allows simultaneously surface deformation, low hydrophobicity and better electroactivity [3]. The present work shows the electrochemical results of interaction between LIG surface of 3D-printed electrode of commercial Acrylonitrile Butadiene Styrene copolymer (ABS), called carbon black (CB), and aqueous solution. It is known that LIG promotes formation of carboxyl, epoxy and hydroxyl on the surface [3], but the oxidation of carbon depends on temperature and ABS/CB quality. Based on Nyquist plot measured data, it was observed that the LIG strategy offers direct formation of electroactive sites of functionalized surface that interacts with water and peroxide due affinity by carboxyl and hydroxyl. However, these reactions might be explained by some limitations due to porous structures presentedin its surface, to temporal electrode roughness and to non-reversible electroactivation. Weconcluded that the LIG technique for ABS/CB can be produce functionalized electrodes without controlled atmosphere and using conventional industrial process. Acknowledgements to UDESC and FAPESC. Influence of Interstitial Oxygen on the Structure, Mechanical Properties, and Biocompatibility of Ti-25Ta Alloys for Biomedical Applications

Edriely Oliveira Saraiva[1], Carlos Roberto Grandini[1]

[1]Universidade Estadual Paulista (*Física*)

e-mail: edriely.oliveira@unesp.br

Currently, technological development has contributed to an increase in the quality of life. However, with the rise in life expectancy, there is a need to construct new medical devices. A noteworthy new class of alloys is the Ti-25Ta alloy, which possesses good mechanical properties and a compact hexagonal (α') and orthorhombic (α'') structure. Ti is a highly reactive element with oxygen at high temperatures, and can naturally form a layer of titanium oxide (TiO2) on its surface. The physicochemical properties of this oxide film areimportant for evaluating the long-term stabilization of the implant and its biocompatibility. The addition of oxygen can induce material hardening, enhancing its biofunctionality, sinceO is a strong stabilizer of the α-phase. The presence of interstitial elements (O, C, N, and H)can alter the mechanical properties of materials, particularly their elastic properties. The main objective of this project is to evaluate the effect of interstitially dissolved O on the structure, microstructure, and selected mechanical properties, as well as the biocompatibility of the Ti-25%Ta alloy, with a view to future biomedical applications. To achieve these objectives, the alloys were prepared by arc melting, laminated at 1000°C, subjected to thermomechanical treatments, and doped with oxygen at three different pressures, characterized chemically, structurally, microstructurally, mechanically, and biologically.

The Arg-Gly-Asp (RGD) motif is a short peptide sequence that recognizes integrins on cell surfaces, stimulating cell adhesion to surfaces [1]. Integrins are associated with cancer progression and metastatic potential of malignant tumors [2] and are overexpressed in circulating tumoral cell (CTCs). Techniques based on the adhesion of CTCs are being studied to develop biomaterials for promoting specific cell adhesion [3]. Immobilizing RGD in a biomaterial may be an approach to promote cancer diagnosis. This study aimed to investigate the influence of each RGD peptide on cell adhesion. Films of 3.5 bilayers were assembled by the layer-by-layer technique. Chitosan was used as polycation, and five different polyanion compositions were tested: modified alginates with arginine (R-ALG), glycine (G-ALG), aspartic acid (D-ALG), a combination of peptides (RGD-ALG) and alginate (ALG) as a blank sample. The film surface was characterized using atomic force microscopy (AFM). Assays for prostate cancer cell (PC3) adhesion were performed to evaluate the influence of peptides on the cell binding film potential. Results showed that all compositions were able to capture cells, although D-ALG depicted enhanced ability to capture cells. This fact can possibly be associated to D-ALG higher film roughness. This study provides valuable insights into the factors that influence the cell adhesion, specifically with RGD motif, highlighting the potential for developing biosensors functionalized with specific proteins.

e-mail: juliana.carvalho@lnls.br

Degradable silica nanoparticles (NPs) have been widely recognized as promising nanoplatforms for biomedical interests due to their ability to degrade selectively, ensuring body clearance and preventing long-term retention. One strategy for degradable NPs development is incorporating redox-responsive sulfide bridges (S-S), reducible by agents overexpressed in tumor microenvironments (TME) [1]. Although the mechanism of NPs degradability is well-known, there are remaining unclear issues concerning the interactions between NPs and relevant biological media that hamper the development of nanomedicine. Blood-based fluids are rich in biomolecules (mostly proteins) that interact nonspecifically with the NPs surface, forming a so-called protein corona (PC) [2]. The presence of PCchanges the NPs chemical identity and triggers biological responses, those that also evolves concurrently with NPs degradation. To-date, the correlation between degradability and the presence of the PC has received little attention in nanomedicine studies. This work elucidated aspects that describe the link between the degradable response of NPs and their subsequent interactions with relevant biomolecules using mainly two types of synchrotron-based spectroscopies (Fourier transform micro-infrared - μ-FTIR and synchrotron radiation circular dichroism - SRCD) and imaging (transmission electron microscopy - TEM) techniques. The results obtained support the hypothesis that the interaction between blood-based components and the NPs have implications for their biodegradability and the impairment of their effective action in TME. Here, we point out the potential of using degradable NPs to advance fundamental nanomedicine research, highlighting the exploitable property of NPs' degradability for biomedical purposes.

e-mail: isabela.lavagnini@usp.br

Hydroxyapatite-zirconia (HZ) composites are promising materials for bone implants due to the combination of high bioactivity and mechanical strength that they present [1]. However, the conventional sintering (CS) process poses a challenge as the different shrinkage rates of different materials can cause micro shear and bending stresses in the composite, leading toa product with low mechanical strength [2]. To address this issue, non-conventional sintering techniques such as Microwave Sintering (MS) [1] and Flash Sintering (FS) [2] canbe employed to achieve rapid shrinkage and densification, avoiding differential shrinkagerates. In this study, we evaluated the densification, microstructure, microhardness, and toughness of HZ composites produced through three different sintering methods: CS, MS, and FS. HZ composite samples with 50wt.% hydroxyapatite/zirconia was formed into a cylindrical shape by uniaxial pressing and then sintered. CS was performed at 1200°C, for 2h, and using 10°C/min; MS was conducted at 1200°C, for 30 min, and using 100°C/min. FSwas performed with a 300 V/cm AC electric field (1000 Hz) and 20 mA/mm² electric currentdensity for 10 seconds (furnace heating rate of 20°C/min). The results showed that the HZcomposite produced by sintering techniques with high heating rates, such as MS and FS, delivers denser materials with higher mechanical properties than those produced by CS. Future studies could focus on optimizing the sintering parameters to further improve the mechanical properties of the HZ composite.

Nanocellulose (NC) is a type of cellulose composed of fibers between 3 and 100 nm in diameter. Due to its biocompatibility, high surface area, mechanical strength, and biodegradability, it is suitable for drug delivery applications [1]. On the other hand, nanoporous silicon (nPSi) consists of silicon nanocrystals embedded in an amorphous porous silica matrix. nPSi is also widely used in controlled drug delivery due to its high surface area (200-800 m2/g), biocompatibility, biodegradability, and bioresorption [2]. In this work, we embedded nPSi microparticles at concentrations ranging from 0. 1% to 1% m/v into NC film matrices to enhance control over drug release kinetics using Methylene Blue (MB) as a model drug due to its antibacterial properties. Our results showed that NC films with 1% m/m released 92% of MB in three hours, while NC films without nPSi released the same amount of MB in 30 minutes. We performed physicochemical characterizations on the samples, including FTIR, DRX, SEM, and stress strength tests. Moreover, we tested the antimicrobial activity of the films, showing their potential for biomedical applications. Finally, we developed a mathematical model based on Fick''s second law to gain insight into the MB transport mechanism into the films.

β-type Ti-Nb alloys are considered attractive metallic materials for long-term bone implant applications [1]. However, metallic implants present poor wear resistance, and the degradation process can be intensified with the friction occurring in corrosive body fluids, such as joint prostheses [2]. Ti-based matrix composites (TMCs) represent promising alternatives for wear-resistant applications because the addition of hard ceramic particles enables to achieve the desired combination of properties. Indeed, the degree of adhesion at the matrix/reinforcement interface is the main factor for achieving the properties, and it can be designed during the composite fabrication when chemical reactions are directly involved in the manufacturing steps, defined as in-situ reactions [3]. Therefore, the present study aimed to produce novel in-situ β-type TMCs with arc-melting process. Initially, Ti-40wt.%Nb alloy was produced by arc-melting. As the second melting step, three TMCs were prepared by adding 5 vol.% of three different ceramic powders: NbC, NbB2, and B4C. The as-cast samples were investigated with optical and electronic microscopy, X-ray diffraction, Vickers hardness measurements, and tribocorrosion tests performed in a phosphate-buffered solution. The results prove the in-situ production, such as the presence of B promoted the precipitation of TiB, and C precipitated as TiC, always embedded in a β Ti-Nb matrix. Thus, the in-situ β TMCs could be produced by varying the type of reinforcement between TiB and TiC, besides the presence of both hard phases. Consequently, the β TMCs demonstrated higher tribocorrosion resistance than the unreinforced β Ti alloy.

Ordered mesoporous silicas (SBA-15) have been proposed as vaccine adjuvants due to their high surface area and pore volume. Besides, it is possible to modify the morphology of SBA-15 just by changing the synthesis conditions. In this study, five modifications of the synthesis conditions were performed to obtain distinct morphologies [1]. Sample 1 (S1) was synthesized by the conventional method, at 40°C and 1000 rpm. Sample 2 (S2) was synthesized under the same conditions, except for the addition of isopropanol. Samples 3 and 4 (S3 and S4) were submitted to 55°C and 35°C stirred at 300 and 500 rpm, respectively, and submitted to static conditions for 24h. Sample 5 (S5) was heated at 30°Cand stirred at 1000 rpm. Samples were characterized by SAXS, SEM, TGA, DSC, NAI, andFTIR and showed an ordered mesoporous structure with similar lattice parameter values.NAI analyses pointed out that the SBA-15 samples have a specific surface area variation from 933.4 (S1) to 587.1 m2g-1 (S4) and pore volume variation from 1.2 (S1) to 0.7 cm3g-1(S4), and similar pore size for all samples. SEM analyses confirmed that different morphologies were obtained, such as rope-shaped aggregated rods (S1), nanospheres (S2), filiform rods (S3), hexagons (S4) and platelets (S5). Through the TG/DSC and FTIR analysis, it was verified that the mesopores are free and with their primordial groups of silanols exposed for the functionalization and incorporation of biomolecules. Thus, it can be concluded that it was possible to modify the morphology of SBA-15 without significantly altering the structural and textural properties, such as, S1 and S2 samples that have distinct morphologies but similar specific surface area, pore volume and pore size distribution. These results qualify these materials for incorporation with vaccine antigens and in vivo immunogenic assays.

e-mail: saraedm1999@gmail.com

Vulvovaginal candidiasis affects about 75% of women, caused by *Candida albicans*. Antimicrobial Photodynamic Therapy is an alternative treatment strategy. Hexadecafluorophthalocyanine is a phthalocyanine (PC) with a potent ability to generate reactive oxygen species (ROS) compared to other PC. Thus ureasil-polyether (UPEO) materials are capable of incorporating hydrophobic molecules, allowing their use in controlled drug delivery systems [1]. The objective of this work was to develop UPEO containing PC against *C. albicans*. The UPEO was obtained from a reaction of modified alkoxide and modified polymers. The infrared spectrum (FTIR) was performed under scanning in the range of 4000-650 cm-1. In vitro evaluation of the antifungal activity was analyzed by the agar diffusion method. The UPEO and UPEO-PC, did not show cracks or precipitates, and the UPEO-PC showed intense blue, the UPEO proved a macroscopic uniformity with a diameter of 1.6 cm and a thickness of 0.2 cm. The spectrum of FITR showed the characteristic bands of PC and UPEO, we highlight the band at 1130 cm-1 referring to the C-N bond of the pyrrole rings and UPEO keeps its bands at 1083 cm-1 (C-O or C-N), and 1642 cm-1 (C=O). In TG, two mass loss events, the first close to 100 °C with 3.12%, related to volatile elements, and the second event between 273 and 510 °C relatedto 67% of mass loss, related to the decomposition of the carbonic structure. The antifungal activity demonstrated that UPEO-PC presented better activity (7 mm inhibition) compared to free PC (without inhibition), this response is relating its solubility increase. The results pointed out that when incorporated into UPEO the solubility is improved as well as the antifungal activity.

Candida albicans causes diseases such as vulvovaginal candidiasis (VVC) affecting ~80% of women at least once in their lives. Antimicrobial photodynamic therapy (aPDT) is based on oxidative photochemical reactions. Hexadecafluorophthalocyanine is a phthalocyanine (PC) that needs a shorter pre-irradiation time to achieve the ideal CFU for clinical use. Nanostructured lipid carriers (NLC) are second-generation lipidic nanoparticles. Hybrid materials (UPEO) maintain the physicochemical properties of dispersed materials [1]. This work aimed to produce NLC containing PC dispersed in UPEO associated with aPDT for VVC. The melt-emulsification method resulted in the carriers without instability events for 90 days. The UPEO obtained by the reaction of modified, alkoxide and polymer, were geometrically equal and the absence of fissures or bubbles. FTIR spectra showed no deletion of clusters and no emergence of new bands indicating that the chemical structures are preserved. The TG showed an improvement in the stability of NLC when dispersed in UPEO, in ~100 ºC the NLC-PC had a mass loss of 85%, when dispersed in the UPEO they presented about 3%. DTA revealed two endothermic events to NLC-PC around 100 ºC referring to the loss of solvents or dehydration. The binary mixture of PC-UPEO or NLC-PC revealed no changes in peak temperature or enthalpy. In the microbiological test by agar diffusion method, with *C. albicans*, the isolated PC did not present an inhibition halo, in the no-light group, the PC-UPEO group showed a 4 mm. In the group with light, AM and PC-UPEO, NLC-PC, and NLC-PC-UPEO showed halos of 10 and 7, 10 and 15 mm, respectively, showing an improvement in the solubility and activity of PC. The formulation produced has the potential to be the treatment for VVC caused by *C. albicans*.

Physico-chemical characterization of six commercial chitosan and impact on antibacterial releasing

Isabela Tavares Rampim[1], Helton José Wiggers[1], Cecilia Zorzi Bueno[2], Pascale Chevallier[3], Francesco Copes[4], Diego Mantovani[5]

[1]Associação de Ensino, Pesquisa e Extensão Biopark (*LBB-BPK*) , [2]Associação de Ensino,Pesquisa e Extensão Biopark, [3]Université Laval (*CR-CHU de Québec*) , [4]Université Laval,[5]Université Laval (*Lab Biomaterials and Bioengineering*)

e-mail: isabela.rampim@alunos.bpkedu.com.br

Chitosan is a biocompatible and biodegradable biopolymer that has high potential to be used as coatings for medical devices to prevent Healthcare-Associated Infections. Despiteits many advantages, there are drawbacks when translating the coatings production frombench to industrial scale. The most notable is the variable quality of raw material, whichbrings difficulties to standardize and ensure consistent quality of finished biomedical products. In this study, six chitosan from different suppliers were characterized and used tosynthetize films with gentamicin according to a previously developed protocol [1]. The aimwas to determine the impact of raw chitosan characteristics, such as molecular weight (Mw)and deacetylation degree (DDA) and purity on film properties and antibiotic release kinetics. Chitosan Mw varied from 110 to 340 kDa, DDA from 82 to 94%, proteins content from 0.14 to 0.49 %, moisture from 7 to 12%, and ash content from 0.6 to 1.5%. This high variability resulted in different films properties, such as thickness, ranging from 20 to 22μm, mass lossin PBS, from 21 to 30% and swelling behavior in PBS, with values varying from 104 to207%. All the synthetized films showed antibacterial activity against S. aureus and E. coli atleast up to 30 days. However, the films exhibited different antibiotic release profiles, ranging from 42 to over 70 days of antibacterial activity. In conclusion, chitosan sourcingimpacts the antibiotic release kinetics on the tested films. Therefore, the characterization ofthe raw chitosan, Mw, DDA and purity, is crucial in determining the final film properties,affecting the final application in terms of short or prolonged release time.

e-mail: adones.rocha@coppe.ufrj.br

The development of new materials for bone tissue engineering is a promising solution to the issue of autogenous replacement. For so, fractures in the bone can be healed using the approach of tissue engineering, which proposes structures to support tissue growing (scaffolds), signaling molecules, and cells combined [1]. The strontium-substituted hydroxyapatite (HASr) is a promising ceramic material used to improve the properties of poly(lactic acid) (PLA) scaffolds [2]. In this work, scaffolds were produced by Fused Filament Fabrication, a simple 3D printing technique, with PLA/HASr filaments obtained using a single-screw extruder. Afterwards scaffolds were treated with NaOH solution (0.01M) at 50°C for 15 min. A Two-Level Fractional Factorial Designed of Experiments wasapplied for the processing parameters in the extruder (2^{5-2}): the three zones temperatures,pull roller speed, and screw speed. The diameter and distribution of ceramic in filamentswere the response variables. The results point out the great effect of Zone 3 and screw speed in response variables. This data was used to produce filaments with 1,76±0,06 mm ofdiameter, with good dispersion of hydroxyapatite, evaluated by SEM. The scaffolds had adimensional accuracy of up to 13.98±1.85 %. Thermal analyses (TGA/DTA) indicate that theaddition of HASr provides thermal stability for the scaffolds, and SEM images show theformation of micropores on the surface of the material. In vitro tests indicated that PLA/HASr scaffolds presented no cytotoxicity.

Acknowledgments: CBPF for gently providing the hydroxyapatite. This study was financed in part by the Coordenação de Aperfeiçoamento de Pessoal de NívelSuperior - Brasil (CAPES) -Finance Code 001 and by the FAPERJ.

PMMA-silica coatings modified with calcium phosphates and silver particles for bioactive protectionof Ti6Al4V alloy

Mayara Carla Uvida[1], Celso Valentim Santilli[1], Anderson Oliveira Lobo[2], Peter Hammer[1]

[1]São Paulo State University (*Analytical, Physical Chemistry and Inorganic Chemistry*) , [2]Federal University of Piauí

e-mail: mayara.uvida@unesp.br

Surface properties play a key role in osseointegration and the long-term performance of implants. In this context, surface modification with coatings has shown to be a promising route to inhibit the release of toxic metal ions and provide bioactive and antibacterial properties [1]. Therefore, this study focuses on the corrosion protection of Ti6Al4V implants using PMMA-silica coatings modified in the near-surface with calcium phosphates (CaPs) and silver (Ag). The hybrids were prepared by the sol-gel process combining the hydrolytic-condensation reactions of tetraethylorthosilicate (TEOS) with the radical polymerization of methyl methacrylate (MMA) and 3-methacryloxypropyl trimethoxysilane (MPTS). CaPs powders of hydroxyapatite (HA) and β-tricalcium phosphate (β-TCP), and Ag nanoparticles were added into the sol-gel phase prepared from the acidic catalysis of TEOS and MPTS. The 12 μm-thick bi-layer coatings are homogeneous, defect-free, and exhibit strong adhesion to the substrate (>12 MPa). The structural properties of the hybrids were evaluated using infrared spectroscopy (FTIR), X-ray diffraction (XRD), thermal analysis, and contact angle measurements. FTIR and XRD results confirmed the formation of the PMMA-silica phase as well as the presence of crystalline CaPs and Ag particles. The higher surface hydrophilicity of coatings (~65°) containing CaPs and Ag compared to bare Ti6Al4V alloy (77°) favors the contact with the tissues. The additives do not affect the structural integrityas evidenced by the long-term stability and high corrosion resistance of the coatings in simulated body fluid (SBF). Electrochemical impedance spectroscopy results of coatings in contact with SBF solution showed low-frequency impedance modulus values of up to 32 GΩ cm^2, remaining for 240 days more than 3 orders of magnitude higher than bare Ti6Al4V.

Polymeric microPLates for sustained drug delivery: Atop-down low-pressure fabrication approach

Bianca Martins Estevao[1], Denise Murgia[1], Paolo Decuzzi[1]

[1]Istituto Italiano di Tecnologia (*Drug, Delivery and Discovery*)

e-mail: bianca_estevao@hotmail.com

Poly(D,L-lactide-co-glycolide) (PLGA) microparticles are a versatile drug delivery platform with several applications in the pharmaceutical field [1]. Our group has developed PLGA-microPLates (µPL) with a square base of 20×20 µm and a 10 µm height. µPL was designedto deliver a broad range of therapeutic payloads, including anti-inflammatory and anti- cancer drugs, small molecules for neurodevelopmental disorders, and RNA nanoparticles for intracellular deposition [2-3]. Herein, the morphological and pharmacological properties of curcumin-loaded PLGA µPL were optimized by introducing new steps in the original fabrication protocol. Specifically, 20×20×10 µm wells, realized by soft lithography in a PVA sacrificial template, were carefully filled with PLGA and curcumin dissolved in acetonitrile. Vacuum suction was introduced to control the solvent removal and also, two different 'pre-purification' steps were tested. Four µPL configurations were realized using PLGA inputs ranging from 2 to 10 mg per preparation. The resulting µPL were characterized by SEM, Confocal, Fluorescence Microscopy, Multir Counter and pharmacological properties were performed via HPLC analyses. Depending on the initial PLGA input, the fabrication yielding ranged between 10 and 70%, the encapsulation efficiency varied from 2 to 13%, and the 1-month cumulative release ranged between 60 and 95%. Higher fabrication yielding and drug encapsulation, and slower release were associated with lower PLGA inputs. In conclusion, a systematic analysis conducted on CURC-loaded PLGA µPL allowed the authors to optimize the fabrication protocol and identify PLGA inputs to enhance morphological and pharmacological properties.

In view of the broad biological application of silver nanoparticles, the production of a lamellar silicate polymer nanocomposite, constitutes an interesting material for study. Thus, the objective of this work is to synthesize and characterize the film composed of the PVP/Bt/AgNP nanocomposite using pvp as a reducing and stabilizing agent for nanosilver. The colloidal suspension was characterized by UV-Vis DLS and zeta potential and FAAS. The thin film was formed and characterized by UV-Vis spectrophotometry. After that, bentonite was added in different proportions and interference in film formation was verified. The film was characterized using DRX, FTIR, SEM, EDS and mechanical tensile tests. The colloidal suspension was obtained and showed stability and a slow silver reduction aspect by PVP. The thin film obtained revealed the non-interference of the drying process in the synthesis of nanoparticles. The films produced showed, through XRD, that there was formation of the PSL nanocomposite. The FTIR indicated the participation of groups containing oxygen and nitrogen, derived from PVP, in the reduction of silver. The surface morphology of the samples was altered with the addition of bentonite and nanosilver. The composition was confirmed by EDS without showing contamination peaks in the material. By mechanical test, the addition of bentonite improved the initial properties conferred by PVP. Thus, it is legitimate to infer that there was formation of a film with adequate properties for biological application.

Shining light on photosensitizers incorporated in lipid membranes

The photodynamic therapy (PDT) has been a promising alternative for treating different carcinomas. However, the lack of detailed knowledge on the mechanisms of action prevents exploitation of the therapy full potential. This work is focused on the photosensitization of lipid membranes and underlying mechanisms of the photodynamic efficiency in the treatment of cancer cells. Specifically, Langmuir and Langmuir-Blodgett (LB) films will mimic the cell membrane of tumor cells, where photosensitizers are further incorporated and subsequently photo-activated. The goal is to investigate the effects of lipid oxidation onthe physicochemical properties of the membrane, which include surface area increase and cleavage of lipid chains. In addition to the traditional surface pressure measurements (π), vibrational spectroscopy techniques are applied to the Langmuir (PM-IRRAS) and LB (FTIR) films in order to elucidate the reaction mechanisms at the molecular-level. The final goal is to correlate the findings at the molecular scale with photodynamic efficiency in complex systems, involving the in vitro culture of cancer cells. The efficiency of the photosensitizers will be quantified using flow cytometry, which will also allow for the determination of the cell death processes that are triggered, including apoptosis, late apoptosis, or necrosis. In summary, this work shines light on the molecular mechanisms of cell membrane photo-oxidation, with broad implications for PDT.

Synthesis and characterization of magnetic MCM-41 applied as drug delivery system

Rafaela De andrade[1], Monique Deon[2], Wilmer José Villarreal Peña[1], Edilson Valmir Benvenutti[1]

e-mail: rafaela.andrade@ufrgs.br

Drug immobilization and delivery systems based on magnetic materials – mainly, iron oxides – have received increasing interest in the last years. The magnetic property adds to the system functionalities such as the possibility to be magnetically carried/separated, to use magnetic energy for heating (hyperthermia treatment) and to use iron as a contrast agent to diagnose (theranostic agents). To provide surface area for drug encapsulation mesoporous ordered silica, MCM-41, can be used because silica is a stable biocompatible material. In this work, a magnetic MCM-41 was synthesized using a modified synthesis with magnetic particles dispersed in the reaction medium. The material was characterized by X-Ray diffraction, Mossbauer spectroscopy, magnetism measurements, N2 adsorption-desorption isotherms and transmission electron microscopy (TEM) images. The X-ray diffractogram in high angles (15 - 80º) and Mossbauer spectroscopy show patterns corresponding to the magnetite and maghemite phases. While in the low angles (1 - 4º) of X-ray diffractogram itis possible to observe the characteristic peaks of hexagonal ordered silica (interplanar distance is about 3 nm) in a large form due to the presence of iron oxide decreasing the long-range ordering. Magnetism measurement show saturation of 10 emu g-1. The N2 adsorption-desorption isotherm is compatible with ordered silica. The obtained surface area (BET method) value is 630 m2g-1 and the pore size distribution (BJH method) shows maximum curve point in 2.7 nm. In TEM images is possible to see the ordered pore structures with larger magnetic particles (about 120 nm of diameter) dispersed in silica. Preliminary drug (chloroquine) encapsulation tests using incipient wetness impregnation were evaluated by fluorescence spectroscopy and it indicates a promising drug delivery system.

Synthesis and evaluation of poly(propylene fumarate)-grafted graphene oxide as nanofiller for porous scaffolds

Andreea Madalina Pandele[1], Matei Raicopol[2]

[1]university politehnica of bucharest (*Advanced Polymer Materials Group*) , [2]university politehnica of bucharest (*Costin Nenitzescu" Department of Organic Chemistry*)

e-mail: pandele.m.a@gmail.com

Recent advances in polymer chemistry enabled the development of advanced scaffolds for tissue engineering. A variety of materials including hydrogels and porous nanocomposites have been investigated as candidates for bone repair[1]. In an effort to obtain porous scaffolds with improved mechanical properties and biocompatibility, the current study discusses nanocomposite materials based on poly(propylene fumarate)/N-vinyl pyrrolidone (PPF/NVP) networks reinforced with polymer-modified graphene oxide (GO@PPF). The GO@PPF nanofiller was synthesized through a facile and convenient surface esterification reaction, and the successfully functionalization was demonstrated by complementary techniques. The PPF/NVP/GO@PPF porous scaffolds obtained using NaCl as porogen werecharacterized in terms of morphology, mechanical properties, sol fraction, and in vitro degradability. SEM and nanoCT examinations of NaCl-leached samples revealed networks ofinterconnected pores, uniform in size and shape. We show that the incorporation of GO@PPF in the polymer matrix leads to a significant enhancement in mechanical properties, as suggested by a decreased sol fraction for the scaffolds containing a higheramount of GO@PPF. Moreover, the surface of mineralized PPF/NVP/GO@PPG scaffolds isuniformly covered in hydroxyapatite-like crystals having a morphology and Ca/P ratio similar to bone tissue. Furthermore, the preliminary biocompatibility assessment revealed a good interaction between PPF/PVP/GO@PPF scaffolds and murine pre-osteoblasts in termsof cell viability and proliferation.

In this study, the main objective was to synthesize iron nitride nanostructures through pulsed laser ablation of a metallic iron target submerged in liquid nitrogen using a Nd:YAG laser [1,2], and to test the nanotoxicity of the samples. Morphological and structural analyses based on transmission electron microscopy (TEM) revealed the formation of monophasic α"-$Fe_{16}N_2$ nanostructures. The produced nanoparticles remained stable for several months in saline solution without any evidence of iron oxides, demonstrating the effectiveness of this method in obtaining a highly complex iron nitride phase [2]. Characterization of the nanoparticles using UV-Vis absorbance and Raman spectroscopy techniques corroborated the TEM analysis, indicating the formation of the iron nitride phase. Due to the reported high saturation magnetization and strong magnetic anisotropy of α"-$Fe_{16}N_2$ nanostructures, suspensions of α"-$Fe_{16}N_2$ nanoparticles in saline solution were tested for biocompatibility in biomedical applications [3]. The nematode ***Caenorhabditis elegans*** was employed as an alternative animal model for toxicity testing. The results indicated that α"-$Fe_{16}N_2$ nanoparticles did not induce toxicity in the nematode, although a reduction in reproductive behavior was observed [3]. This low toxicity suggests a high potential for the use of α"-$Fe_{16}N_2$ nanoparticles as drug carriers and in the development of biosensors for medical treatments and alternative therapies, such as magnetic hyperthermia.

e-mail: marina.abucafy@gmail.com

Cancer treatment remains a significant challenge in the medical field, and the use of innovative materials such as Metal-Organic Frameworks (MOFs) as drug carrier and upconversion nanoparticles (UCNPs) as bioimaging agent, have shown promise in the development of theranostic systems. This study aimed to develop a core-shell material using NaYF4:Yb3+, Er3+ upconversion nanoparticles (UCNP) modified with polyacrylic acid (PAA) and ZIF-8 to evaluate their potential for the controlled antitumor drug release. Physicochemical characterizations revealed that the structures of MOF and UCNP remained unchanged after core-shell formation. Besides that, the luminescence spectra obtained with the excitation at 980 nm by the Yb3+ and Er3+ ions showed that the material has emission in the green and red regions, respectively. The particles of the UCNP-PAA@ZIF-8 material showed an average size of 75 nm, with a 20 nm-thick ZIF-8 shell. Besides that, the porous nanosystem presented encapsulation efficiencies of 57.5% and 68.0 % for methotrexate and doxorubicin drugs, respectively. The release rate was higher in acidic medium (Phosphate-Buffered Saline, PBS, pH 5.0) than neutral medium (PBS pH 7.4) suggesting that the nanocarriers are promising for targeted drug delivery and tumor microenvironment-responsive drug release. In vitro cell viability assays, determined by MTT assay, in MRC-5 and A-549 cell lines with a higher concentration (0.1 mg. mL-1) and incubated for 48 h, showed a cell viability higher than 70 % that confirms the potential of the UCNP@MOF systems as theranostic materials. In conclusion, the multifunctional materials prepared in this work allow the potential application of these core-shell UCNP@MOF superstructures in both treatment and imaging modalities of cancer diagnosis.

Ureasil-polyether hybrid materials as a novel miconazole controlled-release system for the treatment of vulvovaginal candidiasis

Brenda Maria Silva Bezerra[1], Sara Efigênia Dantas de Mendonça y Araújo[1], João Augusto Oshiro Junior[1]

[1]Universidade Estadual da Paraíba (*Programa de Pós-Graduação em Ciências Farmacêuticas*)

e-mail: brendamariasb@outlook.com

Miconazole (MCZ) is an antifungal drug used for the treatment of vulvovaginal candidiasis (VCC). The available formulations of MCZ are unable to control its release and require a high frequency of administration. Ureasil-polyether hybrids are good candidates for controlled-release drug delivery systems and can be molded into different pharmaceutical forms [1]. This study aimed to develop ureasil-poly(ethylene oxide) (U-PEO) and ureasil-poly(propylene oxide) (U-PPO) ovules loaded with MCZ for the treatment of VCC. The hybrids were obtained by the sol-gel method, loaded with 0.135 mg of MCZ, and molded as ovules. Physicochemical characterization was performed by Fourier transform infrared spectroscopy (FTIR), thermogravimetry (TG), and differential thermal analysis (DTA). The activity against ***C. albicans*** ATCC 10231 was analyzed by broth microdilution. The drug release assay was performed in a USP apparatus 2. FTIR and DTA curves did not indicate chemical or physical incompatibilities between MCZ and the tested hybrids. TG curves showed increased thermal stability of MCZ in U-PEO and U-PPO, with shifts above 50 ºC in the main thermal event of the drug. MCZ showed activity at the minimum inhibitory concentration of 2.5 μg/mL. Different release profiles were observed for the hybrids, while more than 50% of MCZ was released from U-PEO in the first 24 hours, about 7% of the drug was released from U-PPO in the same period, reaching ~ 90% and 25% of release within 120 hours, respectively. Thus, our study demonstrated a novel controlled-release system for MCZ based on ureasil-polyether hybrids with the potential to be administered at a lower frequency than the available formulations for VCC.

e-mail: brendamariasb@outlook.com

Curcumin (CUR) and miconazole (MCZ) are molecules with activity against ***Candida albicans***. The synergism between these drugs improves clinical efficacy. Ureasil-polyether hybrids can be used for dual drug delivery in a single pharmaceutical form [1]. This work aimed to develop ureasil-poly(ethylene oxide) (U-PEO) ovules loaded with CUR and MCZ for the treatment of vulvovaginal candidiasis (VCC). U-PEO was loaded with 0.135 mg of CUR and MCZ, and molded as ovules. Physicochemical characterization was performed by thermogravimetry (TG), differential thermal analysis (DTA) and Fourier transform infrared spectroscopy (FTIR). The activity against ***C. albicans***ATCC 10231 was evaluated by broth microdilution. The synergism between the drugs was analyzed by the checkerboard method. The drug release assay was performed with a USP dissolution apparatus 2. TG results showed high thermal stability of CUR and MCZ in U-PEO (>260 ºC). DTA curves did not suggest physical incompatibilities between the drugs and U-PEO. FITR results indicated no chemical incompatibility between the drugs. CUR and MCZ showed minimum inhibitory concentrations (MIC) of 256 and 2.5 μg/mL, respectively. The synergistic effect was proven and MIC values were reduced to 32 and 0.625 μg/mL after the drug combination. In U-PEO/CUR and U-PEO/CUR/MCZ ovules, the release profile for CUR after 24 hours was 48% and 38%, reaching a plateau after 72 hours with 90% and 66%, showing that MCZ influenced the release profile. Our results showed for the first time a controlled-release pharmaceutical form for co-administration of CUR and MCZ as a novel combination therapy for the long-term treatment of VCC.

e-mail: lobo@ufpi.edu.br

To date the application of soft hydrogels to bone and cartilage regeneration is limited due to low mechanical modules (fracture and stiffness). To solve this, cryo(bio)printing surges as an alternative to improve the crystallinity of cross-linked hydrogels. At same time, the lack of oxygenated bioprinted hydrogels construction can generate hypoxia inside hydrogels and promotes cellular apoptosis. Oxygen supply for in vitro cell culture and in vivo 3D bioprinted structures is challenges to improve vascularization inside hydrogels structures. Although some technologies employ oxygen-generating materials to add sufficient oxygen levels, the limitations and challenges of current technologies include the lack of controlled, sustained, and prolonged release of the oxygen. Moreover, the fabrication methods may leave some impurities or residues resulting in toxicity to the cells and low vascularization inside hydrogels constructions. "Click" chemistry is a facile, versatile, and compatible chemical strategy to engineer hydrogels for tissue engineering applications. Herein, we disclose the engineering of oxygen-generating micro/nanoparticles in cells-laden bioinks through a combination of gelatin-methacryloyl (GelMA) and a versatile catalyst-free tetrazine and norbornene inverse electron demand diels-alder click reaction hydrogels. Different layers containing or non-micro/nanofibers were also evaluated looking for improve of mechanical properties. The hydrogels combined GelMA, chondroitin sulfate (CS) and poly(ethylene glycol) (PEG) crosslinked in situ, displaying tunable rheological and mechanical properties after nanofibers mats incorporation (special after three layers), for sustained and prolonged oxygen-release. All biological assays will be discussed and compared to other hypoxic hydrogels constructions reinforced with nanofibers mats.

3D printed Al_2O_3 scaffolds coated with calciumphosphates enriched with strontium

e-mail: esteryukimi@usp.br

Additive manufacturing is being extensively explored in the fabrication of scaffolds for tissue engineering. However, the of the pores obtained is still a challenge. In this sense, this work aims to obtain scaffolds from alumina filaments (Al_2O_3) coated with calcium phosphates (CaPs) enriched with strontium ions (Sr^{2+}) using the biomimetic method. The scaffolds were chemically treated to improve the adhesion of CaPs layer during biomimetic coating. Then, one part was coated with synthetic body fluid (SBF) 5x more concentrated and another part was coated with the same solution enriched with 1.00 mmol/L Sr^{2+}. The scaffolds were characterized by X-ray diffraction, scanning electron microscopy, and X-ray computed microtomography. Furthermore, the release of Sr^{2+}in the SBF solution was studied. It was possible to observe the formation of phosphate phases of biological interest such as α-TCP, β-TCP, HAp, TTCP, and Sr-Hap on the surface of the coated scaffolds. Regarding the morphology of the scaffolds, high porosity and high interconnectivity between pores were observed, with dimensions favorable to osteoconduction, osteoblast growth and vascularization of the tissue. The results obtained show promising properties for targeted applications of these scaffolds in the field of bone tissue engineering.

A drug-drug solid dispersion of mefenamic acid with pyrazinamide

Anderson Pedrosa da Silva[1], Luis Henrique Silva Queiroz[1], Ariene de Morais Alves[1], Paulo Roberto da Silva Ribeiro[1]

[1]Universidade Federal do Maranhão

e-mail: anderson.ps@discente.ufma.br

There are several strategies to improve the solubility and dissolution rate of drugs when these factors are limiting drug bioavailability. Solid dispersions (SD) are used to improve these physicochemical properties of drugs. Mefenamic acid (MFA) is a non-steroidal anti-inflammatory and pyrazinamide (PZA) is an anti-tuberculosis drug. It belongs to classes II and III of the biopharmaceutical classification system, respectively [1, 2]. This work aimed to obtain a new drug-drug solid dispersion of MFA with PZA by the solvent evaporation method. The samples were characterized by X-Ray diffraction (XRD), thermogravimetry (TG), differential thermal analysis (DTA) and differential scanning calorimetry (DSC). The data obtained by XRD evidenced the formation of a SD from the interaction of MFA with PZA in molar ratio 1:1. The TG curve of this material showed good thermal stability up to 132.7 °C (Tonset). The DTA curve showed an endothermic event characteristic of sublimation of PZA at 167.4 °C (Tonset), followed by phase transition, fusion and decomposition of MFA at 183.3, 229.8 and 244.8 °C (Tonset), respectively. The DSC curve presented an endothermic of sublimation of PZA present in SD at 168.1 °C (Tonset), followed by phase transition and fusion of MFA at 183.1 and 230.1 °C (Tonset), respectively. The DTA and DSC curves did not show the phase transition of PZA in SD, indicating the interaction between starting compounds. Thus, this new drug-drug solid dispersion is a promising material to produce more effective drugs for the treatment of inflammations, pain and tuberculosis.

Adsorption of Arginine on Cellulose Nanofibers: Implications for Biomedical Applications

Rafael Giovanini de Lima[1,2,3], Diego Magalhães do Nascimento[2,3], Juliana da Silva Bernardes[2,3]

[1]Universidade Federal do ABC, [2]Brazilian Center for Research in Energy and Materials, [3]Brazilian Nanotechnology National Laboratory

e-mail: rafaelgiovanini96@gmail.com

Effective immobilization of biomolecules is a crucial technology to give materials appropriate functions for biomedical applications. Arginine (Arg) is an amino acid with healing properties. Its incorporation into polymers can lead to innovative materials to treat wounds. Here, we evaluated the adsorption of arginine to TEMPO-oxidized cellulose nanofibers (o-CNF) by force spectroscopy by atomic force microscopy (AFM-FS) and quartz crystal microbalance with dissipation monitoring (QCM-D). The conversion of hydroxyl to carboxylate groups on the o-CNF surface prompts a high surface density of negative charges to promote arginine absorption through the guanidinium group at pH 7. To analyze the electrostatic interaction, spherical AFM probes were functionalized with o-CNF with two degrees of oxidation (160 and 1160 μmol of carboxylate groups per g of cellulose) and their interaction with mica substrate in an aqueous medium was measured before and after the incubation in an Arg solution (0.1% m/m). During the tip approaching, the repulsion between the mica surface and o-CNFs tips becomes evident at approximately 200 nm and reaches a maximum between 15 and 35 nm. For lower (higher) charged nanofibers, a force of 0.10 nN and 0.04 nN (0.23 nN and 0.11 nN) was measured before and after arginine adsorption, corresponding to a decrease of 60% (52%) in the repulsion force and confirming the interaction between -COO_ and guanidinium groups. Furthermore, the repulsive profile of the force-distance curves after ARG incubation suggests that the ARG molecules shield not all carboxylates. In situ adsorption of Arg onto o-CNFs was analyzed by QCM-D. The mass increment of the o-CNF sensor was measured after 10 minutes of an Arg solution (0.1% m/m) flow, preliminary results indicate that the ARG adsorbs on o-CNF. This study suggests that the incorporation of Arg molecules into o-CNFs has the potential to create materials with sustained release of ARG to promote healing.

Adsorption of chlorhexidine by highly charged synthetic mica (Na-mica-4): a possible antibacterialmaterial

e-mail: alanicaro@gmail.com

Microbial resistance has become a worldwide concern due to the possible human and animal health complications these microorganisms can cause [1]. Controlled drug release systems have been carried out as an alternative, mainly using clay minerals as the delivery vehicle [2]. Thus, this work aims to study the formation of new hybrids based on chlorhexidine and highly charged synthetic mica (Na-mica-4). The materials were characterized by XRD, their adsorption potential of mica with chlorhexidine at different concentrations was analyzed, and the final material was applied in an antibacterial assay against bacteria against ***Staphylococcus aureus***ATCC 25923 (Gram-positive) and ***Escherichia coli***ATCC 25922 (Gram-negative). The XRD standards for Na-mica-4 and hybrids with chlorhexidine did not show significant differences in the reflection peaks, mainly those corresponding to the (001) plane, with values at 2θ = 7.30º (1.2 nm), indicating that chlorhexidine interacts on the outer surface of the clay mineral. The maximum amount of incorporated/adsorbed chlorhexidine was 552 mg g^{-1}, indicating good interaction between the species, with the best fit being the Freundlich model, with an R2 of 0.97. Thus, in the results of antibacterial activity, it was observed that the chlorhexidine/mica material obtained an inhibition rate of 100% against S. aureus and E. coli, thus indicating a possible new antibacterial material.

Acknowledgments: The authors thank CAPES, CNPq, and FAPEPI.

Advances in electrochemical modification of Nb surface for applicability in metallic biomaterials

ANA FLAVIA BEZERRA[1,2], Leonardo Contri Campanelli[2], Danieli Aparecida Pereira Reis[2]

[1]Universidade Federal de São Paulo (*Engenharia e Ciencia dos Materiais*) , [2]Federal University of Sao Paulo

e-mail: ana.flavia02@unifesp.br

Nb2O5 is a promissing ally for implantable biomaterials and eletro-optical applications, pizeoeletric materials fibers, catalysis and biossensor. Low cost techniques should be considered for Nb2O5 production. In this review, different conditions of eletrochemical anodization of pure niobium (Nb) will be considered for the formation of Nb2O5, under constant voltage applied to the surface of Nb, a growing pit forms over time and with different electrolyte types, resulting in the Nb2O5 layer. The results will be discussed based on ethylene glycol + NH4F+ H2O 4%, 60min, voltage range from 2 to 20V, temperature of 50 ±0,5°C, in vivo cell adhesion tests compared to potential voltage limits of 200 to 250V, for 2M OOCH3, 0.1MH3PO4, and 2M EDTA solution, galvanostatic and galvanostatic/potenciostatic regimes, 60s, 300s or 30 min, current density of 350mA/cm2, and post-anodization chemical etching using 9M H2O2 and 0.3M HCl at 75 °C for 30min. The formation of the Nb2O5 oxide layer is observed under all electrochemical conditions, with fracture occurring only at 250W. Post anodization chemical corrosion, allowed significant in vitro cell adhesion and the addition of nano-roughness to the micro-pures of the surface. Cell proliferation was by confirmed in vivo. Further studies are suggested to investigate chemical corrosion on the oxide surface.

A major worldwide challenge is the prevention of Health Care Associated Infections (HCAI). Environmental screening confirms that pathogenic microorganisms can persist for a long time, contaminating items, equipment and "common" area in hospital causing se-rious infections and epidemic outbreaks [1]. To mitigate public health risk, the main strat-egies include the disinfectants' usage and high Touch Surfaces (HTS)' cleaning which could be regarded as a critical vehicles for bacteria via hands [2]. However, these methods ap-pear ineffective to inhibit bacterial growth and often detergents use may lead to envi-ronmental consequences, as well as increasing the risk of the onset of resistances. This ev-idence justifies the increased interest in the identification of new approaches based on antimicrobial coatings on sanitary surfaces [3], likely made of nanomaterials, to reduce microbiological contamination.
The objectives of this study are: i) the development and characterization of new antimi-crobial nanostructured removable polymeric coatings (AMC) for healthcare setting sur-faces, based on chitosan and polycaprolactone formulations; ii) the evaluation of in vitro efficacy of the innovative AMC, iii) the preliminary on site validation of the developed AMC, by its application on HTS (i.e. bed side table or bars) in hospital rooms.
Results show that the developed AC samples are effective in reducing bacterial growth, even in common indoor environment conditions. Furthermore, in vitro results show that a rapid bactericidal action obtained by using the new developed nanoparticles is a very important aspect for the correct identification of the active coatings to be used.

Tissue engineering is recommended as a promising therapy for tissue repair and can be effectively used in nerve, bone and skin tissues (DONG; MA; GUO, 2020). Polylactic acid (PLA) is a polymer with good biocompatibility that can be used in bone tissue engineering. Chitosan, in turn, has antimicrobial activity and is indicated for use in biomaterials. Methacryloyl gelatin is also a versatile biomaterial with tunable properties and compatibility for use in tissue engineering (HUANG et al., 2021). This work aims to research the state of the art in order to verify publications (patents and articles) consolidated in the literature on the functionality of applied hydrogels. The technological prospection was carried out in three databases: ESPACENET, USPTO and WIPO. These databases were selected due to their accessibility and reliability of available data. The search for journals was carried out on the main platforms, namely: Web of Science TM, Scopus and Scielo. Data collection was performed in February 2023, using descriptors, keywords and terms: "suture", "hydrogel", "chitosan" and "poly(l-lactic acid)". large number of deposits in the years 2015 and 2020 inthe EPO base, both with 23 patents deposited. China is the most advanced and developed country in hydrogel and chitosan sutures, with a total of 54 patents deposited, followed by the United States with 43, the base of WIPO with 42 and Canada with 24 deposits, of which countries and organization with greater quantity and progress when it comes to this area.

Colorectal cancer is currently the third most prevalent cancer type worldwide and is responsible for the second-highest number of cancer-related deaths. To address this issue, novel therapies are being explored to efficiently destroy cancer cells while minimizing adverse side effects. Photodynamic therapy (PDT) is a non-invasive therapeutic modality in which a photosensitizer (PS) is applied to trigger cancer cell death through photochemical mechanisms. Rose Bengal (RB) is an amphiphilic PS from the xanthene family that exhibits high quantum yield in singlet oxygen ($^1O_2$) generation, which is a reactive specie that can oxidize biological structures. Herein, we evaluated the effect of RB on cell membranes of colorectal carcinoma (Caco-2) by assembling Langmuir monolayers on concentrations ranging from 1 to 25 × 10^{-6}mol/L. The photodynamic efficiency of RB was also investigatedat different concentrations (0.5 to 25 × 10^{-6}mol/L) and incubation periods (0.5, 3, and 24hours) on in vitro culture of Caco-2 cells. The viability of cells was assessed by MTT assays24 h after 1-h irradiation at 525 nm (32.3 mW/cm2) in in vitro experiments. The results ofLangmuir films indicated that RB interacts with membrane lipids, leading to their photooxidation upon irradiation and suggesting a possible damage to the cell membrane. MTT assays demonstrated that concentrations above 5 × 10^{-6}mol/L reduced the cell viabilityby 80%, irrespective of the incubation period. In summary, RB has shown potential as a photosensitizer in the photodynamic therapy of colorectal cancer.

Bioactive three-dimensional scaffolds inspired by bone extracellular matrix

Petrus do Nascimento Kirsten[1], Bianca Chieregato Maniglia[2], Ana Paula Ramos[1]

[1]Universidade de São Paulo (*FFCLRP - DQ*) , [2]Universidade de São Paulo (*IQSC*) *e-mail: petrus.kirsten@usp.br*

Carrageenan (Carr), a group of natural sulfated polysaccharides extracted from red algae of the Rhodophyceae family, has been widely applied in tissue engineering [1]. Its use is justified by the similar chemical structure compared to glycosaminoglycans, a matrix of polysaccharides present in the bone extracellular matrix [2]. Carr is capable of forming thermoreversible gels and its gelling behavior depends on the molecular characteristics of each Carr group, i.e. the amount of sulphate groups, and the addition of electrolytes [3]. Thus, the objective of this study was to synthesize and characterize 3D biomaterials containing Carr with improved properties to stimulate the biomineralization of osteogenic cells. In the first part of this study we analyzed the mechanical properties of hydrogels and membranes containing 3 and 5 wt % of κ- and ι-Carr with the addition of KCl, NaCl, and CaCl2 as crosslinkers. With the aid of a texturometer, we evaluated the mechanical behavior of the hydrogel and the stress, strain, and Young''s modulus of the membranes. The results showed that κ-Carr forms stronger materials when compared to ι-Carr. Even more, higher concentrations of Carr results in higher strength and resistance values. Also, each electrolyte acts differently on the groups of Carr, depending on the formulations as hydrogels or membranes. As next steps, we intend to evaluate the osteogenic properties of these samples in 3D osteoblasts cultures and their respective bioactivity and biodegradability. Summing up, we will correlate how different structures of Carr-based biomaterials affect the mechanical properties and the osteogenic, bioactive and, biodegradable properties.

Biological evaluation of gelatin biomaterial viewingskin tissue engineering

Carolina Kafka Neves[1], Christiane Bertachini Lombello[1]

[1]Universidade Federal do ABC (*CECS- Centro de Engenharia, Modelagem e Ciências Sociais Aplicadas*)

e-mail: carolina.kafka@aluno.ufabc.edu.br

In some adverse scenarios of the human organism, the skin healing process might not happen naturally. As a consequence, the wounds originated can evolve to the chronic stage, where there is a deficiency of the natural production of collagen [1]. For that reason, the biomedical industry has a need to seek alternatives that can stimulate skin regeneration, such as biomaterials, biomolecules and cellular therapies based on tissue engineering. Biomaterials based on hydrolyzed collagen, also known as gelatin, are commonly used for tissue engineering studies because of its biocompatibility and biodisponibility, moreover, it can be used as a scaffold for cell culture [2]. Thus, this project had the objective to carry out cytotoxicity assay with the gelatin biomaterial, during a period of up to 2 days with Vero cells culture in a 12-well plate. Following the formation of the cell monolayer, fragments of the gelatin were incubated to the culture and, after 48 h, the inverted light microscopy was held to analyze the cell morphology, characterizing the qualitative cytotoxicity of the biomaterial. The microscopy analysis did not show any kind of morphological changes in the cells, which had the standard elongated shape with the presence of round nucleus and nucleoli. Hence, the experiment executed during the development of this study evinced that hydrolyzed collagen is more beneficial for the skin tissue engineering area, because of its cost, the favorable properties and the cell's response to it. Going further, other studies can be performed viewing the combination of biomolecules, e.g. growth factors, with the tridimensional structure of the gelatin biomaterial.

Biomaterials in health sciences are becoming more constant to treat bone-related problems caused by chronic joint diseases in the elderly, diseases and deformities that affect growth in childhood, traumas caused by traffic accidents, and others.[1] For these biomedical applications, bone substitutes and grafts require a set of properties, such as biocompatibility, angiogenic, and osteoinduction potential, biological safety, adequatemechanic properties, and high stability.[2] In this context, calcium polyphosphate (CPP) emerges as an alternative to develop bone biomaterials because it has biocompatibility, low toxicity, osteoconductive, osteoinductive, and osteogenic potential, as well aspresents controlled porosity. Despise those characteristics, the properties of CPP-based medical devices can be enhanced, by adding other additives, such as polymers (e.g.,alginate) and nanoparticles (e.g., silver nanoparticles - AgNPs), to improve their mechanical and antibacterial properties, respectively.[3] Therefore, this work pretended to develop CPP-based materials for bone applications, incorporating alginate and AgNPs.The results showed that AgNPs presented spheric morphology and antibacterial potential against E. coli and S. aureus. Diffractometry results revealed that composites have crystalline phases of hydroxyapatite, dicalcium phosphate, and tricalcium phosphate. The biomaterials based on CPP, alginate, and AgNPs were characterized by FTIR and SEM, confirming the formation of the composites, which have the potential to be used as antibacterial biomaterials for bone applications.

Buriti oil in obtaining polyurethanes: a new approachto biocompatible materials

Thátila Wanessa Vieira de Sousa[1], Fernando Silva Reis[1], Ewerton Gomes Vieira[2], José Milton Elias de Matos[1]

[1]Universidade Federal do Piauí, [2]Instituto Federal de Educação, Ciência e Tecnologia doMaranhão

e-mail: thatila.wanessa@gmail.com

Recent studies have investigated the potential of buriti for developing healing formulations due to its ability to accelerate the tissue regeneration process and reduce inflammation as oil or polymer. Among these, polyurethanes are a class of polymers that find applications in industrial areas and medicine due to their excellent properties. However, the synthesis of polyurethanes usually requires the use of toxic and non-renewable petrochemical materials, leading to environmental concerns [1]. Therefore, researchers have been exploring sustainable alternatives for the synthesis of polyurethanes [2]. In this context, the work proposes the use of buriti oil in the manufacture of biocompatible polyurethanes. The monoacylglycerol (MAG) was obtained by reacting buriti oil and glycerol, in the molar ratio 1:2, in the presence of the catalyst LiOH and confirmed by FTIR. Polyurethanes were synthesized from MAG in the presence of hexamethylene diisocyanate (HDI) and polyethylene glycol (PEG).Acknowledgements: FAPEPI, CAPES, UFPI, LIMAV.References: [1] Pacheco, I. K. Purpose/Aim: Develop a sustainable bovine hydroxyapatite dental ceramic with the addition of titanium dioxide (TiO2) nanoparticles (5% and 8% by weight), and analyze the outcome of this addition to the microstructure, mechanical and chemical properties, according to the International Organization for Standardization (ISO) 6872:2015 for dental ceramics.. Materials and Methods: Disks (Ø = 14 ± 2 mm; thickness = 1.2 ± 0.2 mm) were obtained through uniaxial and isostatic pressing from bovine hydroxyapatite powder and TiO2 nanoparticles and sintered at 1300ºC for 2h. Three experimental groups were developed (HA, HA+5%TiO2 and HA+8%TiO2) and microstructurally characterized by X-ray diffraction (XRD) and scanning electron microscopy (SEM). For mechanical and chemical analysis, indentation fracture toughness (IF), biaxial flexural strength (BFS) and chemical solubility tests were performed. Results: XRD spectra revealed the appearance of a peak corresponding to b-tricalcium phosphate (ß-TCP) for HA group. For HA+5%TiO2 and HA+8%TiO2, the entire composition was converted into ß-TCP and calcium titanate (CaTiO3). The SEM images showed a dense ceramic matrix and a uniform distribution of another phase in groups with TiO2 nanoparticles. IF toughness was higher for HA+5%TiO2 (1.34 ± 0.26 MPa.m1/2) and HA+8%TiO2 (1.28 ± 0.21 MPa.m1/2) than for HA (0.65 ± 0.10 MPa.m1/2). HA showed significantly higher characteristic stress (295.8 MPa) in comparison to groups with 5% (235.1 MPa) and 8% (214.4 MPa) TiO2 nanoparticles. Differences were not observed between the Weibull modulus values. The solubility results indicated that all experimental ceramics were above the 2000 ug/cm2 limit set by the ISO 6872:2015. Conclusions: The experimental calcium phosphate ceramic with additions of 5% and 8% of TiO2 achieved desirable mechanical properties, but the chemical solubility values did not allow it to become a dental ceramic.

Characterization of alterations in the lipid fraction of microencapsules enriched with açaí lipid extract

FERNANDA GENY CALHEIROS SILVA[1], Ticiano Gomes do Nascimento[2], Camila Braga Dornelas[3], Giselda Macena Lira[4]

e-mail: fernandagenycalheiros@gmail.com

The açaí (Euterpe oleracea) presents itself as a berry fruit widely consumed and with antioxidant capacity related to its lipid composition. Lipid antioxidant substances are highly labile, which requires research around drying techniques such as spray-dryer and freeze-drying in order to increase shelf life and minimize the decomposition of compounds. The microencapsulates were formulated from the pulp of frozen natural açaí from a local supplier. For preparation, defrosting was performed under refrigeration and filtration toseparate the aqueous extract from the gummy portion. The gum was used to promote solvent extraction under maceration, to obtain the lipid fraction (control group). The extractwas subjected to spray-drying, stufa with air circulation and freeze-drying. Of the microencapsulated, lipid fraction and composition study were obtained, being el and s: ultraviolet scanning of the samples, gas chromatography, high performance liquid chromatography, DPPH and TBARS antioxidant assays, FTIR and thermal assays. Among the findings, it was possible to identify, in açaí oil, a composition rich in unsaturated fatty acids,as well as tocopherols and carotenoids, in addition to evidencing that drying techniques act directly on this composition, preserving it, in the case of lyophilization, and degrading it, in the case of drying in an oven and by spray-dryer, due to hyperthermic exposure , being evidenced, although the exposure to UV light caused greater degradation of lipid fractions, culminating in the identification of degradation products and reactive oxygen species. In terms of antioxidants, açaí oil showed high activity (dose-dependent) and the TBARS assayalso showed that lipid oxidation was more evident in samples submitted to heating, with greater formation of malonaldehyde, highlighting the benefits of freeze-drying in this vegetable oil.

Characterization of bioactive glass/$Co_XFe_{3-X}O_4$ superparamagnetic nanocomposites and their potential application in bone cancer treatment by magnetic hyperthermia

e-mail: juliana.soares@aluno.ufabc.edu.br

Bioactive glasses have been applied in bone tissue repair and regeneration due to their biocompatibility and osteogenic properties. If these glasses are designed to display magnetic properties, they can also be applied in bone cancer treatment by magnetic hyperthermia, thereby coupling bone regeneration and cancer therapy. This work aimed at synthesizing nanocomposites consisting of cobalt ferrite nanoparticles ($Co_XFe_{3-X}O_4$, X = 0.15, 0.12, and 0.06) dispersed in a matrix of a sol-gel-derived bioactive glasses based on the $58SiO_2$-$33CaO$-$9P_2O_5$system. The structural and magnetic properties of the nanocomposites were characterized by scanning electron microscopy coupled with energy dispersive spectroscopy (SEM-EDS), X-ray diffraction (XRD), and vibrating sample magnetometry (VSM-SQUID). The scanning electron microscopy and X-ray diffraction results confirmed that the nanoparticles are embedded in a nanoscale glass matrix, thus forming a nanocomposite. Magnetic characterizations evidence their superparamagnetic, highlighting exchange interactions among the magnetic nanoparticles within the nanocomposite. Calorimetric measurements of the nanocomposites showed a proper heating behavior for magnetic hyperthermia. The developed superparamagnetic bioactive nanocomposite display tuned magnetic properties compared with other similar materials published in the literature, which are addressed to cobalt doping. Then, they are promising materials for applications in bone cancer treatment allied with bone regeneration.

Titanium alloys that contain non-toxic elements such as Ta, Mo, Nb and Si are interesting for biomedical applications, as they combine high corrosion resistance, biocompatibility and mechanical resistance. The lifetime of an implant also depends on its surface properties, which can be improved by growing TiO_2 nanotubes through the anodizing process [1]. In this study, Ti-35Nb-5Ta alloys were electrochemically anodized in order to evaluate the formation of nanostructured layers and the corrosion resistance of the alloys. Surface characterization was performed by scanning electron microscopy (SEM) coupled to an energy dispersive spectroscopy (EDS) probe, X-ray diffraction (XRD) and atomic force microscopy (AFM). Electrochemical characterization through polarization curves and electrochemical impedance spectroscopy in simulated body fluid (SBF) [2]. The results indicated that it is possible to grow TiO_2 nanotubes from the parameters used in the anodizing process. Nanotubes were observed throughout the surface of the samples, in addition to good uniformity of the layer and good regularity of the diameter of the nanotubes. The anodized samples showed high resistance to corrosion, due to high values of polarization resistance and corrosion potential, in addition to low values of corrosion and passivation current densities. Thus, anodized Ti-35Nb-5Ta showed sufficient corrosion resistance to be used in implants.

Combining Photothermal (PTT) and Photodynamic (PDT) Therapies for Enhanced Therapeutic Efficiency on Skin Cancer Cells

Mirella Boaro Kobal[1], Sabrina Aléssio Camacho[2], Karina Alves Toledo[3], Pedro Henrique Benites Aoki[1]

[1]Universidade Estadual Paulista (*Departamento de Biotecnologia*) , [2]Universidade Estadual Paulista, [3]Universidade Estadual Paulista (*Departamento de Ciências Biológicas*)

e-mail: mirellabkobal@gmail.com

Cancer is one of the leading causes of mortality worldwide. Skin cancer, which accounted for 19.3 million cases in 2020, constitutes one-third of all diagnosed cancers. In the quest for minimally invasive clinical treatments, light-based therapeutic approaches such as photothermal (PTT) and photodynamic (PDT) therapies have been explored. Metallic nanoparticles act as photothermal agents, converting light into heat, leading to cell death through hyperthermia. Meanwhile, photosensitizers (PS) generate reactive oxygen species (ROS) upon light stimulation, triggering cell death through oxidative stress. The synergistic combination of PTT and PDT has been proposed as a strategy to enhance therapeutic efficacy by leveraging their dual effects. In this study, gold nanoparticles were coated with silica (AuSHINs), conjugated with the PS methylene violet 3RAX (VM), followed by a second silica layer, resulting in the nanostructure named AuSHINs_VM_SiO_2. UV-Vis spectroscopy confirmed the maximum absorption bands of both VM and AuSHINs in the green region, at 555 nm and 527 nm, respectively, enabling the simultaneous activation of PTT and PDT. AuSHINs with VM were verified by DLS, zeta potential, TEM and Raman measurements. From these experiments, the monodispersity were confirmed, resulting in the synthesis of nanoparticles with a diameter of 13 nm and, after coating and conjugation, 24.45 nm. Subsidiary experiments of temperature increase and generation of singlet oxygen ($^1O_2$) were performed for AuSHINs and AuSHINs_VM_SiO_2 by irradiation at 525 nm. Thus, they showed a temperature increase of about 14°C and the VM demonstrated efficiency as a PS agent ($\Phi_\Delta {}^1O_2 = 0.157$). The therapeutic efficiency of these nanostructures will be evaluated on in vitro cell cultures derived from primary (A375) and metastatic (SH-4) melanoma compared to PDT and PTT by MTT assays.

Titanium alloys are widely used for biomedical applications due to their excellent mechanical properties, biocompatibility, and corrosion resistance. However, the presence of alloying elements such as vanadium (V) and aluminum (Al) can negatively affect their biocompatibility [1]. Therefore, there is a growing demand for titanium alloys without V and Al for use as biomaterials. These alloys must have adequate mechanical properties, along with high biocompatibility and the ability to integrate with bone tissue. This study compares the corrosion behavior of heat treated Ti-12Mo-13Nb alloy at 950°C/1h, Ti-12Mo-13Nb as cast, commercial pure Ti (cp-Ti) and Ti-6Al-4V alloys by potentiodynamic polarization tests. The Ti-12Mo-13Nb alloy ingots were produced using an arc-melting furnace with non-consumable tungsten electrode under argon atmosphere. Corrosion resistance tests were carried out in Ringer's solution (pH = 7.0) using an electrochemical cell set up with a working electrode (samples), a counter electrode (Pt) and a standard calomel as the reference electrode. The electrochemical tests were conducted using potentiodynamic polarization applying potentials from -2000 mV to +2000 mV in relation to the open circuit potential (OCP). From the polarization curves, the corrosion potential, pitting potential and corrosion current were determined. The results indicated that the Ti-12Mo-13Nb alloys is less susceptible to corrosion mechanisms compared to commercially pure Ti (control) alloys. Therefore, the Ti-12Mo-13Nb alloys can be considered as an interesting alternative for biomedical applications, as it does not contain potentially cytotoxic elements and showed satisfactory anti-corrosive properties in electrochemical test.

e-mail: jady.JLFS@gmail.com

Coordination complexes of transition metals containing mixed ligands have been studied intensively due to their promising applications in different fields [1]. Therefore, the development of computational studies of these complexes is also important and has been performed using density functional theory (DFT) [2]. The objective of this work was to develop a theoretical study of the geometrical, thermodynamical, and electronic properties of the complex of Cu(II) with maleate and 1,10-phenanthroline ligands. The software Gaussian 16 was used for the development of the electronic structure calculations, employing the DFT functional PBE1PBE combined with the 6-311++G(d,p) for H, N, O, and C atoms, using the SDD pseudopotential and basis set for the Cu atoms. From the optimized geometry obtained in a triplet state, a slightly distorted square pyramidal geometry is observed around each metal center, in good agreement with experimental results [3]. Calculated values of Gibbs free energy and enthalpy of the complexation are negative, indicating that the process is spontaneous and exothermic. The HOMO and LUMO are concentrated over the maleate and phenanthroline ligands, respectively. The gap between the β-HOMO (the true HOMO) and LUMO is 4.69 eV and this value was used for chemical reactivity indices such as chemical potential, hardness, softness and electrophilicity, that indicated that the electronic structure of the complex is stable. The computational results showed the binuclear coordination structure of Cu(II) and indicated that the complexation reaction is spontaneous and exothermic.

Acknowledgments: We thank the FAPEMA, CAPES, CNPQ for supporting this research.

Abstract

Although there is a plethora of 245 different zeolites with different frameworks with unique and unusual topologies of channels and cavities with large applications in the field of industrial catalysis [1], few of them have found systematic biomedical applications, especially for the purpose of hemorrhage control. Hemostasis is a complex biochemical process in which the assembly of substrates, enzymes, protein cofactors and calcium ions ona phospholipid surface accelerates the rate of coagulation. Several inorganic solid matrices have been employed as topic hemostatic agents, and among them zeolites [2]. However, the synthesis of enriched calcium zeolites for the purpose of hemorrhage control and using as raw materials chicken eggshell biomass is an unexplored field of research. We report the data of the synthesis of four calcium zeolites using $CaCO3$ derivated from chicken eggshell. Thromboelastographic results using the pristine calcium enriched zeolites show that they were able to promote a faster clot formation and a higher maximum clot strength than those of the commercial topical hemostatic agent QuikClot.

Titanium and its alloys are widely used for implants manufacturing and biomedical devices, due to their high corrosion resistance and biocompatibility. In this work, the study of the corrosion resistance and structural characterization of a Ti-29Nb-13Ta-4Mo β-Ti alloy was carried out. The alloy was investigated in as-received state and after several passes of equal channel angular pressing (ECAP). In ECAP, a metallic specimen is pressed though a metallic die containing two channels, equal in cross section area, intersecting at a die angle, where it is constrained and bent through a sharp angle which imposes high plastic shear strain in material without any reduction in cross-section area. ECAP was performed using a die with 120º between the channels. The processing was performed at 350 ºC up to 8 ECAP passesby route A, into which the specimen is not rotated between each ECAP pass. The sampleshad their microstructures analyzed by SEM/EBSD and XRD while the corrosion resistancewas evaluated by potentiodynamic polarization tests. The interplay between the ECAP processing, microstructure and corrosion performance is discussed in this work.

Among the manufacturing techniques to regenerate damaged tissues are electrospinning, widely used to make nanofibrous muscle mimetic supports for tissue regeneration, and 3D bioprinting has also been used to manufacture muscle tissues in recent times [1]. Cartilage has a very limited ability to self-repair after traumatic injuries, representing a heavy socioeconomic burden. Regenerative biomaterials can create a favorable local environment for cartilage repair without causing relevant regulatory and scientific concerns of cell-based treatments [2]. Gelatin methacrylate (GelMA) is a versatile matrix that can be used to create tissue structures ranging from vasculature to cartilage and bone, has good biocompatibility, solubility and degradability [3]. PVA is a cheap, water-soluble, non-toxic and biocompatible polymer, often used in biomedical applications. For these reasons, and due to its excellent wiring capacity, PVA is often considered to be excellent in microfribas electrowiring processes [4]. Based on the above, this work aimed to develop a biomaterial structured in alternating layers between electronically rotated PVA fibers and bioprinted GelMA at low temperatures, creating a multilayer scaffold. Characterizing the material with mechanical, chemical and biological tests, thus achieving a scaffold with good mechanical strength higher than 15kPa compatible with the inserted medium and optimal cell viability.

Nanoparticles have been used in several applications, due to unique properties, such as elevated surface area, conductivity, small size, and optical features [1]. Namely, silver nanoparticles (AgNPs) have attracted much interest in biomedical applications due to their anti-inflammatory and antibacterial properties, which provide excellent healing inactivating various microorganisms. Additionally, AgNPs are widely used to produce biomaterials that will be in direct contact with the human body, however, for their synthesis, the main reducing agent used is sodium borohydride($NaBH_4$), wich presents high toxicity[2]. Therefore, this project aims to develop a more biocompatible synthetic route to prepare biomedical applications. For this, sodium citrate was used as a stabilizer, $AgNO_3$ as a silver source, and ascorbic acid as a reducing agent. The pH was maintained at 11 and the reaction occurred at 50 ºC for 30 minutes. The samples were characterized by UV-Vis spectroscopy, and the spectra showed only one band 410, indicating the formation of spherical AgNPs. However, the absorbance presents a lower intensity, varying form 0.6 to 1.0, when compared to the AgNPs formed in the presence of $NaBH_4$ (absorbance around 2.0), indicating a lower concentration of AgNPs. Thus, more tests will be made to optimize procedure, testing different stabilizers and physicochemical parameters. Nevertheless, our results indicate that this synthetic route is promising to obtain more biocompatible AgNPs, ideal for biomedical applications.

Bone diseases and fractures are among the most common orthopedic problems and represent an important global health problem and have been the subject of current studies. The standard clinical treatment used to repair fractures and bone defects is bone grafting (autograft, allograft), but they face major challenges due to the lack of donors for bone transplantation, costs, and risk of disease transmission [1]. Thus, it is essential to develop an alternative device, capable of mimicking the characteristics of the extracellular matrix, providing an appropriate microenvironment to facilitate the organization of cells, and thus, control and direct the formation of a new tissue, which is the objective of this work [2]. A porous bioactive scaffold was synthesized from monoacylglyceride (MAG), derived from buriti oil (Mauritia flexuosa). Buriti oil (BO) contains a high concentration of monounsaturated fatty acids, carotenoids, polyphenols, and bioactive substances with high antioxidant and healing capacity, which makes it an excellent raw material for tissue engineering. The scaffold synthesized from the reaction between MAG, obtained by glycerolysis reaction, and polyethylene glycol (PEG) in the presence of hexamethylene diisocyanate (HDI) was confirmed by FT-IR, thermal stability by TG and DSC, morphological evaluation by SEM and the presence of BO components confirmed by UV-VIS. Development of zinc alloys by powder metallurgy for application as biomaterial

EMANUELLA CARVALHO DOS SANTOS[1], Alysson Martins Almeida Silva[2]

[1]Universidade de Brasília (*Instituto de Química*) , [2]Universidade de Brasília (*Engenharia Mecânica*)

e-mail: emanuellafabricia32@gmail.com

Biodegradable metals have been developed for application as biomaterials with the advantages of gradual degradation, avoiding secondary surgeries and offering better mechanical properties when compared to ceramic and polymer materials [1]. Zinc is a daily essential chemical for the human body and plays a key role in human health. The human body requires about 15 mg/day of zinc, which proves that zinc has good biocompatibility for the human body and is therefore safe for biomedical applications, in addition to being considered a biodegradable metal [2]. Synthesis by powder metallurgy and more, the study of mechanical properties, microstructure and composition of zinc matrix alloys was carried out by Differential Scanning Calorimetry (DSC), to define alloy sintering temperature, Vickers hardness, X-ray diffraction (DRX), X-ray fluorescence and microtomography respectively. The DSC analysis indicated the sintering temperature of the samples that were synthed with a heating rate of 15 K/min to 553 K for 2 hours and a natural cooling stage of 553 K to room temperature. XRDs reveal a zinc matrix with a compact hexagonal crystalline structure of space group P63/mmc. Furthermore, the hardness tests show an increase in hardness with an increase in the concentration of the dopant, boron and a decrease with an increase in the porosity profile of the samples, a profile obtained by microtomography.

Direct observation of the transformation of amorphous calcium carbonate to calcite using cryo-transmission electron microscopy techniques

Noemi Raquel Checca Huaman[1], Alexandre Malta Rossi[1], André Rossi[1] [1]Centro

Brasileiro de Pesquisas Físicas (*COMAN*)

e-mail: noemiraquelchecca@gmail.com

Calcium carbonate ($CaCO_3$) is a frequently used model mineral in studies of crystallization mechanisms. Where the diversity of the origins, composition, morphologies, and polymorphs of $CaCO_3$ makes it a material with high potential in applications biotechnological. Crystalline $CaCO_3$ exhibits three polymorphs: hexagonal vaterite, orthorhombic aragonite, and rhombohedral calcite, in order of increasing thermodynamic stability. The physical properties of $CaCO_3$, such as structure, shape and polymorphism, is strongly correlated with the crystallization pathways underlying their formation [1]. Due to the stochastic nature of nucleation and growth, the effective route to understanding is to directly capture the building blocks as they interact and crystallize. In this work, a systematic study of the different steps of $CaCO_3$synthesis was performed using cryo-transmission electron microscopy (Cryo-TEM) in the modes of HRTEM, SAED, EDS and EELS. This technique allows preservation of 3 µL of the specimen by vitrification at different stages of the synthesis process, preventing their modification during drying. For the synthesis of $CaCO_3$we use $CaCl_2.2H_2O$ (1M) and Na_2CO_3(1M) what were obtained from Sigma Aldrich. Aqueous solutions of the reactants was made using milli-Q water. In vitro evidence is provided for the transformation of amorphous calcium carbonate (ACC) to calcite throughthe mechanism of dissolution-reprecipitation. Therefore, using a synthetic system, we provide evidence for the transformation of ACC into calcite in highly supersaturated solution. While our reaction conditions are significantly different from those used by organisms during biomineralization, our results demonstrate that this non-classical pathwayis a possible route for the precipitation of the thermodynamically more stable phase of $CaCO_3$.

e-mail: carlos.constantino@unesp.br

Bisphenol-A (BPA), present in the composition of polycarbonate plastics and epoxy resins, the main materials of household items such as cups and bottles, is considered an emerging pollutant since it affects the human endocrine system, influencing the action of hormones in the body [1]. However, the health risks of chronic exposure to BPA are not yet understood in detail. An efficient way to obtain conclusions about the effects of compounds such as BPA on the body is the study of its interaction with mimetic systems of cell membranes (composition and), such as lipid vesicles. Here we investigated the action of BPA on giant unilamellar vesicles (GUVs) formed by a mixture of the phospholipid DOPC and cholesterol, ensuring both chemical composition and fluidity of eukaryotic cells. The GUVs composed by DOPC/cholesterol in the ratio 8/2 in mol were formed by electroformation and analyzed under a confocal microscope. When exposed to BPA, the GUVs presented fluctuations and several morphological deformations, such as: i) change of the spherical shape, ii) bud transition (formation of two smaller vesicles from a larger vesicle), and iii) formation of lipid cords. The morphological changes were observed within 2 minutes after the addition of BPA to the GUVs, with the contaminant causing a stress on the curvature of the vesicles, disturbing the integrity of the membrane. Therefore, this work highlights the importance of understanding the effect of BPA on structures that preserve both the and the curvature of the cell membranes, being suitable indicators of its action on biological processes.

Cobalt-chromium (CoCr) based alloys are biocompatible, resistant to corrosion and non-magnetic, turning them interesting as biomaterials in the biomedical field [1]. However, little is known about its effect on cell metabolism, which motivated this study. Firstly, CoCr discs [subjecting (W) or not (Wo) to dual acid-etched (DAE)] were incubated into FBS - free cell culture medium up to 24 h (37 °C). This CoCr-enriched medium was further used to treat shear-stressed endothelial cell cultures up to 72 h. Thereafter, the conditioned medium containing metabolites of shear-stressed endothelial cells in response to CoCr-enriched medium was further used to subject osteoblast's cultures, when the samples were properly harvested to allow the analysis of the molecular issues. The CoCr-enriched medium was found to modulate the metabolic pathways of both cells, inducing the expression of genes such as HIF1α, VEGF, nNOS, osteocalcin and bone sialoprotein. Furthermore, shear stresson endothelial cells increases the activity of matrix metalloproteinases in bone cells [1,2]. Altogether, our data shows for the first time that shear-stressed endothelial metabolites responding to CoCr discs contribute to osteogenic phenotype *in vitro*, and this predicts an active crosstalk between angiogenesis and osteogenesis during osseointegration of CoCr alloy and bone healing, maybe guided by the Co-induced hypoxic condition.

In recent decades, biomaterials have become increasingly important in the field of medicine. Being used to supply lost or diseased biological structures to improve the quality of life of the patient [1]. HAp electrodeposition on titanium alloys has shown to be a promising technique to improve the biocompatibility and osseointegration of orthopedic implants [2]. The present work aims to analyze the deposition of apatite on the Ti-35Nb-7Zr-5Ta alloy via electrodeposition. The HAp solution was prepared, and the process was carried out for two different periods: for 2h and 4h with heating at 70 °C. In both Ramann Spectroscopy analyzes, both for 2h and 4h, the peak at 960 cm-1 is noted, being a typical point for calcium phosphate, attributed to the vibrations of the phosphate and hydroxyl present in the hydroxyapatite. EDS analysis of HA-Ti-35Nb-7Zr-5Ta confirmed the presence of titanium, calcium, phosphorus, tantalum, sodium and niobium for both the 2h and 4h processes. This composite biomaterial is known for its excellent biocompatibility and mechanical properties. Titanium is widely used in medical applications because of its biocompatibility and corrosion resistance. Calcium and phosphorus are essential components of hydroxyapatite, which is a natural material found in human bones. Tantalum and niobium are refractory metals with high resistance to corrosion and oxidation. It was shown that the results obtained by SEM show that, during the periods of 2h, 4h there was the formation of tetracalcium phosphate (TTCP), it can be noticed the elongation of the apatite with the increase of the period. In addition, it was possible to observe, by the morphological aspect of the surface, the gradual and constant transformation of the material. And, with the effectiveness of the deposition of apatite in the alloy, we can see the excellent biocompatibility of the material.

The interest in studies involving the development of intelligent wound dressings for chronic wounds has been gradually growing, since they constitute a serious public health problem. In this context, nanofibers are highly attractive due to their characteristics, such as low cost, high surface-to-volume ratio, porosity, flexibility and simple processing [1]. Furthermore, the possibility of combination with different compositions and properties allows for varied applications. In particular, poly (vinyl alcohol) (PVA), a semi-crystalline, hydrophilic polymer, widely used due to its biocompatibility and biodegradability properties [2] In the present work, silver nanoparticles were synthesized by the chemical reduction method by salts and incorporated into PVA fibers, which were obtained by electrospinning. The physicochemical and morphological properties of the nanofibers were investigated.Scanning electron microscopy (SEM) images indicated nanofibers with homogeneity and nanometric diameter. Furthermore, it was possible to observe an average diameter of 68.57 nm for silver nanoparticles (Ag-NP) that, when incorporated into the electrospun PVA mats, remained at nanometric scales, which can be evaluated by SEM and Energy Dispersion X-Ray Spectroscopy (EDS). It was also possible to observe that Ag-NP incorporated at lower concentrations into PVA nanofibers demonstrated rapid biodegradability, indicating their potential for application where immediate releases are required. Therefore, Ag-NP/PVA nanofibers can be an interesting alternative for use in biomedical applications.

Electrospun collagen nanofibers can mimic the architecture of native human tissues, making them an attractive option for tissue engineering applications [1]. Collagen nanofibers are inherently mechanically weak, which may limit their use in load-bearing applications [2]. To overcome this limitation, collagen is commonly cross-linked or blended with synthetic polymers to improve mechanical strength without compromising biological activity [3]. In this work, we report the use of the ecological solvent acetic acid for electrospinning of the type I collagen blend from bovine skin with polyvinyl alcohol (PVA) with the aim of increasing the mechanical strength of the resulting scaffold and preserving the biological activity of the collagen. Characterizations of the polymers and membranes were performed by Fourier Transforms Infrared (FTIR), X-ray Diffraction Analysis (XRD) and Scanning electron microscopy (SEM). The results indicated that the presence of collagen results in samples with a less crystalline structure. Blending PVA with collagen improved the spinning property and mechanical properties of the composite fibers. The PVA-Collagen membrane exhibits an FTIR spectrum that indicates the PVA and collagen components by comparing their respective wave numbers. The characteristics of the collagen bands, Amide I, II and III and the acetate group of PVA were identified. Nanofibers in the range of 100-200 nm, whereas solid-state characterization showed the successful integration of collagen with PVA.

Emissive complex between 4'-N,N-diethylaminoflavonolin octa-acid deep-cavity cavitand and Rhodamine 6G

Lilian Camargo da Luz[1], Fabiano da Silveira Santos[1], Fabiano Severo Rodembusch[1]

[1]Universidade Federal do Rio Grande do Sul (*Instituto de Química*)

e-mail: liliancmrg@gmail.com

The investigation of the chemistry of the excited state plays a crucial role in the field, as it relies on intermolecular communication. This aspect holds significant importance in materials science research. To explore the interaction in such systems, we investigated the ground and excited states of 4'-N,N-diethylaminoflavonol (DEA3HF) in an octa acid-based (OA) confined medium in the presence of Rhodamine 6G (R6G). It is worth mentioning that the solubility of organic compounds is often limited to organic solutions, so the use of the supramolecular approach, which involves confining them in a capsule without affecting their photophysical properties, significantly expands the study and applications [1]. For this purpose, fluorimetric titrations were performed using steady-state and time-resolved fluorescence spectroscopy in different environments. Despite the observed spectral overlap between the flavonol emission and the R6G absorption, as well as the fluorescence quenching of the flavonol in the presence of R6G, the almost constant fluorescence lifetimeat different amounts of R6G discards the presence of FRET. Steady-state and time-resolved fluorescence indicate the formation of an emissive complex between the proton transfer dye encapsulated within water-soluble supramolecular host octa acid (DEA3HF@(OA)2) and R6G. The respective Stern-Volmer plots corroborate these observations, suggesting a static quenching mechanism, which the formation of an emissive complex in the ground state.[2]

Nanogels are promising drug delivery systems for the treatment of different diseases, being of great interest for new alternative antiparasitic therapies, in order to overcome the various limitations found in current chemotherapies for leishmaniasis, such as high toxicity and resistance. Curcumin (CUR) has a vast antiparasitic activity, however, its applications are limited, since it is an unstable molecule, which can be degraded by light and temperature, in addition, the low solubility in water reduces its bioavailability [1]. Despite some biological limitations regarding its absorption in the body, encapsulation of curcumin in nanogels based on epoxy polyetheramine, are non-toxic, biodegradable, biocompatible and represent an effective strategy to deliver CUR in a controlled and selective manner. The aim of the present study was to develop an effective, non-toxic and biodegradable polymeric drug delivery system encapsulating curcumin for the treatment of cutaneous leishmaniasis. the specificity of nanogels. Nanogels showed advantages in CUR transport and release, including increasing the stability of the molecule and delaying its degradation.

Polymersomes are a type of synthetic vesicles formed by a polymer membrane that surrounds an aqueous inner cavity. Their colloidal stability and membrane permeability determine their potential applications,[1] including drug delivery and biochemical reactions in confined spaces.[2] The membrane permeability is typically governed by the chemical nature and length of the hydrophobic segment. In this work, we investigated the self-assembly of a variety of diblock copolymers using thin film hydration (FH) and solvent-switch (SS) approaches. Accordingly, the block copolymers were dissolved in a suitable organic solvent. In the case of FH, the solvent was evaporated, and the formed thin polymer film was hydrated using PBS solution. As for SS, PBS was dropwise added into the organic polymer solution. The systems obtained were characterized by dynamic (DLS), static (SLS) and electrophoretic light scattering. In all cases 0.2 mg/ml polymerosome solutions in PBS were measured. SLS was measured from 30 to 150° with 5° stepwise increase and DLS was measured at 90°. Nanoparticles with ranging from 75 to 160 nm were obtained, and the structure sensitive parameter ρ= RG/RH~1 suggested the formation of polymer vesicles. This is also corroborated by the determined values of Nagg (Nagg~10^3) commonly obtained for polymersomes. We have ongoing research to study the permeability of different polymersomes to different analytes. For small molecules such as rhodamine, we conduct encapsulation and release assays. We also investigate their permeability to solvents via light-scattering experiments, and we are simultaneously exploring the proton permeability using pH-responsive probes.

Nanotechnology presents a breakthrough in the discovery and exploration of the physical and chemical properties of new promising materials for numerous scientific applications. The use of nanomaterials applied to bone regeneration, for example, have become the target of studies in bone tissue engineering. In particular, nanomaterials based on niobium such as polyoxoniobates (PNb) have been attracting great interest due to their high solubility in water, low toxicity on the human body and provide greater bioactivity of bone cells. The PNb´s have osteoinductive properties, being indicated as a material that allows to promote osteogenesis and angiogenesis, and, therefore, promising to repair defects and favor osseointegration.

Recent research shows that polyoxoniobates have versatile properties due to their antimicrobial action against resistant organisms, bioactivity, high levels of adhesion and osteoblasts proliferation [2]. Thus, the objective of this work was to associate the antimicrobial and osteogenic properties of the Nb nanocomposite to favor and improve osseointegration. The physicochemical properties of the material were investigated using SEM, FTIR, TG, RAMAN, DLS, and in vitro assays to assess osteogenic, antimicrobial, and antioxidant activity.

Recently, interest has grown in treating cancer with natural products, including bee venom or aptoxin (APX). APX, due to its main constituent, melittin, induces cytotoxic, antitumor, immunomodulatory and apoptotic effects in different cells in vitro and in vivo. However, the toxicity of apitoxin and the nonspecific hemolytic effects make its clinical application unfeasible. Hydrogels are materials capable of absorbing and releasing large amounts of fluids according to predetermined factors such as pH, temperature, time, among others. Polyvinyl alcohol hydrogel (HPVA) is a new material that can be an interesting alternative for drug administration due to its biocompatibility and ability to absorb and release substances with both positive and negative charges. In addition, it is a chemically inert material, which are the main characteristics for the development of a platform (dressing) for drug release. Melanoma is the most serious skin cancer with high mortality rates due to its highly invasive and aggressive nature. The search for new topical treatments can collaborate with the local treatment of this type of cancer with less systemic effects. Thus, this work evaluated the potential for absorption and release of APX conjugated to HPVA for future analyzes using cultures in two and three dimensions (2D and 3D). HPVA was characterized by FTIR and SEM. The apitoxin was diluted in PBS at a concentration of 2.5 mg/mL and incubated with 10 mg of HPVA at 37 ºC for 48 h. The ability to absorb and release the main components of APX (melittin and phospholipase) was evaluated by UV-Vis at different times. The best results were observed after 48 hours of incubation, where 44% of the melittin and 50.7% of the phospholipase present in the solution were absorbed by the HPVA. Release was on average 50% of both melittin and phospholipase absorbed. The results are preliminary, however the HPVA/APX presents excellent possibilities to composea curative for the treatment of melanoma.

Exploring the photothermal efficiency of gold-shell isolated nanoparticles on triple negative breast cancer cells

Sabrina Aléssio Camacho[1], Pedro Henrique Benites Aoki[2], Osvaldo Novais de Oliveira Junior[3], Christelle Prinz[4]

e-mail: sabrina.alessio@gmail.com

With 2.3 million new cases per year, breast cancer stands as the top malignancy affecting women worldwide. In this scenario, the growing occurrence of triple negative breast tumors poses a significant challenge for treating patients. Triple negative cancer cells do not express the receptors estrogen (ER), progesterone (PR), and human epidermal growth factor 2 (HER2), being therefore, more aggressive and difficult to treat than other cancer subtypes. In the search for more efficient, less invasive and low side effect treatments, photothermal therapy (PTT) has drawn attention. Photothermal agents convert light into heat, leading to cell death via hyperthermia and can generate reactive oxygen species(ROS), which induce oxidative stress in the cell membranes. Herein, gold shell-isolated nanoparticles (AuSHINs) are applied as photothermal agents to target MDA-MB-231 cells, a human breast adenocarcinoma cell line derived from metastatic breast cancer patients and classified as triple-negative cancer cells. AuSHINs incorporation and cellular localization was assessed by flow cytometry and confocal fluorescence microscopy, respectively. The photo-efficiency of AuSHINs is more reliant on light dose than incubation time. When exposed to 20 and 30 min of irradiation, the viability of cells incubated with AuSHINs for 0.5h decreases from ca. 77% to 16%, while for 2.0 h of incubation, the viability decreases fromca. 70% to 12%. The light doses also affected the cell death pathways. After 20 min irradiation, most of the non-viable cells are in early apoptosis. In contrast, after 30 min, the cells progress to late apoptosis, and the viable cells decrease drastically. Intracellular ROS was also detected and found to increase with the incubation time. These findings can help in comprehending the response of triple-negative breast cancer cells to PTT and may lead to the exploration of novel treatment strategies.Acknowledgements: CNPq, FAPESP, and the Crafoord Foundation.

Facile glycerol-isopropanol synthesis route of nanostructured $Mg(OH)_2$ and MgO doped with Calcium-based nanoparticles

e-mail: lobrazuna@gmail.com

New research advances in bone tissue regeneration showed a key role in ion-doped biomaterials' function with ceramic scaffolds. The addition of Ca ions is essential to supply Ca^{2+} ions to/from the cellular media, also magnesium Mg^{2+} ions stimulate osseointegration by increasing bone-implant contact, push-out force, and new bone formation [1]. In this work, we report the synthesis and characterization of $Mg(OH)_2$ and MgO nanoparticles (NPs) doped with calcium for biological applications. The glycerol-urea (GU) method was developed by our research group, and it is an innovative and efficient method for the synthesis of metallic hydroxy/oxides [3], although for this study the urea was replaced by isopropanol (GI) for better conditions for later large-scale production. The syntheses were carried out using $Mg(NO_3)_2{\cdot}6H_2O$ and NaOH in a 3:1 mol ratio of G:I solution under stirring at 70°C, with addition of 0.001, 0.005, 0.01 and 0.05 mols of $CaCl_2{\cdot}2H_2O$. To obtain MgO,the samples were calcined in a muffle oven for 3 hours in 400°C. Structural characterizationwas performed by X-Ray Diffraction. Results showed formations of brucite ($Mg(OH)_2$) and calcium carbonate ($CaCO_3$), with crystallites of 10 and 100 nm respectively, this formation has several advantages for biomedical applications, such as: biocompatibility, sensitivity to pH, low cost, biodegradability, and low cytotoxicity [3]. TEM and SEM images showed NPs' morphology of sheets and shells with high surface area. ICP-OES data will be used to assess the amount of calcium ion release from NPs. These initial results already show the great potential of this material for biomedical applications.

Analysis of shot peening associated to plasma nitriding surface layers on austenitic stainless steel are conduced to verify the influence of the surface treatment in fatigue behavior. Shot peening can be used to increase fatigue resistance, due to the surface residual stress induced. Additionally, shot peening can be used as a previous plasma nitriding treatment to improve nitrogen atoms diffusion, increasing the layer hardness, thickness and fatigue resistance [1]. Thus, the aim of the present work is to study the effect of previous shot peening surface treatment in plasma nitrided F138 stainless steel fatigue properties. Specimens treated with plasma nitriding and shot peening associated to plasma nitriding were analyzed in high cycle fatigue tests. Previous shot peening treatment to plasma nitriding promoted a failure in lower strength values than reference specimens, and its similar to plasma nitride specimens. The result can be associated to roughness increase due to shot peening and plasma nitriding treatments, which can influence fatigue behavior as other surficial morphological characteristics of the formed layer [2]. Fracture surface were analyzed by scanning electron microscopy (SEM) and ductile fracture surface was observed in all conditions. In higher load conditions cracks and microcraks were formed on the sides of the specimen.

Essential oils are molecules with intense bioactivity, and their uses in several fields of industry, such as health and food, have been explored [1]. However, the high volatility of essential oils limits their use [1,2]. Therefore, incorporating essential oils in solid materials is a strategy to maintain their properties. This study investigated the incorporation of Nerolidol at 50% v/v concentration in raw and organophilic bentonites. The antibacterial action of the oil/clay hybrids against *Staphylococcus aureus*and *Escherichia coli*was also evaluated using the direct contact test. XRD patterns confirmed the intercalation of the oil in sodium bentonite, increasing the basal spacing of 1.26-1.50 nm, and in the cetyltrimethylammonium clay (CTAB-Bent), which value was 3 nm. FTIR spectra concord with the interaction between the oil and OH and organic groups in raw and organophilic samples, respectively. The antibacterial of the hybrids revealed 100% inhibition for both bacteria. Promising results indicate that obtained hybrids materials can be used in cosmetics and health products.

Abstract

Surface modification of Ti implants can improve their performance. It is known that the formation of a nanostructured oxide layer on Ti surface improves its osseointegration [1]. In this work, electrochemical anodization was used to obtaining of nanostructures on Ti-53Nb, with low and high O content, Ti-13Nb-13Zr and Ti-6Al-4V alloys. The Ti substrates were manufactured by powder bed fusion techniques. Two different electrolytes were used for anodizing: organic and aqueous. The nanostructures were characterized by scanning electron microscopy (SEM) and grazing-incidence X-ray diffraction. Nanostructures were obtained on the Ti alloys surface for both electrolytes. The nanostructures presented higher inner diameters but lower thickness when formed using an aqueous solution. The nanostructured oxide layer on the titanium surface did not present a crystalline arrangement. A relatively high O content in the Ti-53Nb substrate caused disorganization in the nanostructured layer. For the Ti alloys substrates with $\alpha+\beta$ microstructure, perpendicular nanostructures to the substrate plane similar to walls were observed, besides perpendicular nanostructures of these walls. The experimental results indicate that the nanostructure growth rate depends on the chemical composition of the crystalline phase.

Functionalization of titanate nanotubes (NtsTi) and application in antibacterial activity

cristiane Pilissão[1], Amanda Alves da Cruz[1], Gustavo Henrique Couto[1]

[1]Universidade Tecnológica Federal do Paraná (*DAQBI*)

e-mail: cristianepi@yahoo.com.br

Nanomaterials exhibit exciting properties, such as high surface area and chemical stability, showing broad applicability. TiO2-based nanomaterials, such as titanate nanotubes (NtsTi), have been extensively studied in the literature due to their exceptional properties, including drug release, photocatalytic activity, and, most notably, their ability to coat bone implants with biological activities [1]. NtsTi can also be functionalized through the reactivity of OH groups on their surface, including silanization using 3-aminopropyltriethoxysilane (APTEs), which adds an amino-silane group, increasing its dispersibility and antibacterial properties [2]. In this study, we proposed the functionalization of NtsTi with APTEs to evaluate its antibacterial activity against S. aureus and E. coli. The NtsTi were obtained through alkaline hydrothermal synthesis using a Teflon reactor and mixing 1g of TiO2 in 100mL of 10 mol L-1 NaOH heated at 120°C for 24h. Excess alkali was removed, and the solid was washed with 0.1 mol L-1 HCl until pH three and then with deionized water until neutral pH. For functionalization, 150mg of NtsTi was dispersed in 100mL of toluene, added 3.5mL of APTes, and refluxed at 80°C for 8h. The functionalized NtsTi was washed with toluene/ethanol. The material was analyzed by Fourier Transform Infrared Spectroscopy (FTIR), Transmission Electron Microscopy (TEM), Scanning Electron Microscopy (SEM), X-Ray Diffraction (XRD), and evaluation of antibacterial properties. The analysis confirmed the formation (NtsTi) with anatase crystalline phases, referring to crystallographic planes (101) and (200), and the functionalization of nanotubes (NTsTi-NH2) with a diameter between 7 and 10 nm. Additionally, both materials showed an inhibitory response to bacterial growth at concentrations of 25 and 50mg L-1; considering the diameters of the inhibition halo, the samples are resistant to bacteria.

The development of materials on a nanoscale has been driven by advances in technology that can provide materials capable of performing a specific role. As a result, titanate nanotubes (TiNT) are nanomaterials with high biocompatibility, porosity, surface area, and excellent photocatalytic properties. However, the challenge encountered for this material is related to its natural tendency to agglomerate, which can reduce the effectiveness of its properties. Therefore, surface modification with the amino group can contribute to electrostatic interactions, increasing the contact area and facilitating cell adhesion. In this work, titanate nanotubes were functionalized with different concentrations (0.2, 1, and 2 % (v/v)) of 3-aminopropyltriethoxysilane (APTMS) to determine the best functionalization parameter to obtain the best material property. Morphological changes were evaluated by scanning electron microscopy (SEM-FEG), infrared spectroscopy (FT-IR), Raman spectroscopy, and X-ray diffraction (XRD). The results showed that there was no effective functionalization at higher concentrations (samples with 2% and 1%) because silica formation occurred on the material's surface, which was unsatisfactory. However, at a concentration of 0.2%, it was observed that the tubular morphology of the TiNT was preserved after surface modification, and the results of FT-IR, Raman, and XRD showed the presence of functional groups on their surface. Therefore, the parameters used in the sample with 0.2% APTMS were considered the most suitable for this study. Acknowledgement Fapesp process 2020/12507-6.

Glycerol based solvents providing ZnO particles

The Glycerol-Urea method (GU) is quite excellent for synthesizing ZnO NPs with well-defined size and morphology, and presents great versatility, allowing the control of morphology by using additives [1]. In this study, urea, a key component in the synthesis, was replaced by other isostructural solvents (isopropanol, tetramethylurea, dimethylurea and thiourea) and/or simply bubbling ammonia in glycerol. The aim was to evaluate whether such modifications could bring improvements and gains to the glycerol-based method. For the Glycerol-Isopropanol (GI), the molar ratio of the solvents was varied, reaching at an optimal one for 10:1. The GI ZnO NPs presented spherical morphology and well-defined size and distribution (similar to the GU method). The approaches with Glycerol-Dimethylurea and Glycerol-Tetramethylurea showed ZnO NPs with reduced size, and the Glycerol-Thiourea mixture resulted in a different compound expected: ZnS. Bubbling ammonia into glycerol resulted in ZnO needle-like morphology. The characterizations were carried out with XRD, SEM and MET, and the results were satisfactory, showing that alternatives to urea are useful and can bring synthetic improvements, in addition to obtaining different structures and even a different product, as was the case of ZnO nanoneedles and ZnS.

Nanomedicine applies nanotechnology to healthcare, addressing challenges such as bacterial adhesion to medical devices. Antimicrobial nanostructures, including graphene, offer advantages such as low toxicity, overcoming resistance, and reduced cost [1]. This study aimed to obtain graphene oxide (GO) and evaluate its antimicrobial and antibiofilm properties for biomaterial coatings. GO was synthed from graphite using the modified Hummers-Offeman method [2], which involves oxidation and exfoliation. Graphite and GO were analyzed by X-ray diffraction, revealing the presence of graphene oxide sheets. The antimicrobial tests followed the protocol by Trentin et al. (2013) [3]. Chemical composition analysis indicated the introduction of functional groups characteristic of GO during oxidation. Thermogravimetry showed good thermal stability of GO, with minor variations at higher temperatures. Scanning Electron Microscopy (SEM) of GO revealed characteristic sheet structures with roughness. For the antibacterial evaluation of graphene oxide, concentrations ranging from 1.5 mg/mL to 0.1 mg/mL were tested against Staphylococcus epidermidis and Escherichia coli. The lowest concentrations exhibited greater inhibition of E. coli biofilm, with 0.1 mg/mL inhibiting 55.3% and 0.5 mg/mL inhibiting 56.7%. S. epidermidis did not show inhibition. The results suggest that GO has potential for modifying medical device surfaces, demonstrating 55.3% inhibition of E. coli biofilm. Future prospects involve combining graphene oxide with PMMA for antibacterial coating formation.

The proliferation of different pollutants caused by anthropogenic activities has become a significant global concern, as they cause severe health and environmental harm. In this context, the amount of waste disposable by different industries causes a real disorder. Many industries disposable different types of waste, and the search for an economical way to reuse it is the major challenge. Then, the development of new sustainable, low-cost alternative use of industrial waste or co-products using non-classical material is a necessary change [1]. In this context, the agroindustry produced a huge amount of waste that are incorrectly discharged [2]. Considering that, this research performed a green chemical synthesis of calcium nanoparticles using eggshell from agroindustry for dentistry applications. These nanoparticles were synthesized using a heat synthesis using different times (7, 15 and 24 hours). In addition, they are fully characterized by UV Visible, FTIR, XRD spectroscopies, Zeta Potential, and morphology analysis (SEM, DLS). The results showed nanoparticles in the range of 202.27-404.23 nm using DLS for nanoparticles by 15 and 24 hours. The charge using Zeta Potential showed a positive charge, but very close to zero point (2.58 mV), which was line with morphological results obtained by SEM, showing a clustering formation. FTIR showed that nonsignificant changes are perceived in different calcium nanoparticles. In addition, the XRD showed a crystallinity characteristics of calcium oxide. These results showed a great potential for this innovative calcium nanoparticle based on waste from agroindustry for dentistry applications.

Silver has been used for medicinal purposes for thousands of years by ancient peoples due to its antibacterial, antifungal, and antitumor properties [1,2]. In this work, the (C2H5AgNO2)NO3 crystal was synthesized by a slow evaporation method. The X ray diffraction (XRD) technique and the Rietveld method, confirms that the material grew in a monoclinic system with P21/a-space group [3]. Thermal properties were analyzed using thermogravimetry (TG), differential thermal analysis (DTA), and differential scanning calorimetry (DSC) techniques. The XRD data collected as a function of temperature revealed that the material undergoes a phase transition at 390 K, transitioning to the triclinic crystal system with the P1-space group. In addition, the vibrational modes were investigated by Fourier transform infrared spectroscopy (FTIR) and assigned using density functional theory (DFT). The findings suggest that the material is promising for applications in antitumor drugs.

A wound is a disturbance of the tissue''s standard shape and function. Skin disruption happens in skin lesions due to physical, thermal, or chemical damage or certain underlying medical or pathological conditions. Gram-positive, sphere-shaped bacteria such as Staphylococcus aureus are a significant health issue due to their multidrug resistance (MDR). Methods for delivering bactericides straight to incisions are being researched. Chemical and photochemical compounds such as safranin and phenothiazines are excellent options for attacking bacteria through chemical and photochemical mechanisms. However, the water solubility and rapid release restrict their effectiveness. In this study, a new hybrid biomaterial was created that combines bacterial cellulose (BC) hydrogel and cellulose nanofibers (CNF) for use as a local drug delivery implant for skin treatments using safranin, which has excellent antimicrobial action against Gram-positive bacteria. CNF increased the safranin load by around two times more than safranin only incubated in BC, indicating a kinetically controlled release mechanism. Bacterial cellulose was also efficient in adsorbing phenothiazine radical cation and its corresponding oligomer, which is promising for application in photodynamic therapy.

Hydroxyapatite deposition on Ti6Al7Nb alloy through electrodeposition and biomimetic method

This work investigates the deposition of calcium phosphate on the Ti6Al7Nb alloy by two methods: biomimetic and electrodeposition. The Ti6Al7Nb alloy was divided into three groups: one containing only substrate; in the second group, a film of $Al_2O_3$was deposited on the samples with a thickness of 100 nm and in the third, the same film was deposited, but with a thickness of 200 nm. The deposition was performed using the Atomic layer deposition (ALD), which forms thin films that protect the titanium surface [1]. A 5× SBF (simulated body fluid) solution was prepared and the samples were immersed in an incubation period for 7, 14 and 21 days. Another HAp solution was made for electrodeposition. The alloy groups were immersed in the solution and left for a period of 4 hours with heating at 70°C. Raman spectroscopy and X-ray diffraction (XRD) confirmed the presence of HAp and tetracalcium phosphate (TCCP) in the alloy after electrodeposition and SBF processes. The EDS identified the chemical compositions of the apatites in the alloy and the Scanning Electron Microscopy (SEM) showed the crystals formed from the apatites [2]. Both techniques were effective in the deposition of HAp, however, electrodeposition is faster, while SBF lasted up to 21 days for some groups of samples.

Human bone tissue has attracted considerable public health concern, due to an increase in the number of bone injuries. Hence, biomaterials are used to repair or replace bones when spontaneous repair may fail [1]. Poly(ether-ether-ketone) (PEEK) is a biomaterial used in orthopedic implants because of its biocompatibility, good tribological properties, and mechanical properties closer to that of human bone [1]. Therefore, this work aims to prepare PEEK nanocomposites by extrusion, with hydroxyapatite (HA), to increase the osseointegration of the matrix, and zinc oxide in spherical (cZnO) and flower (fZnO) morphologies, for tribological reinforcement. The nanoparticles' effect was verified individually, with simple nanocomposites, and simultaneously, with hybrid nanocomposites by mixing HA and ZnO. The specimens were tested by scratching tests in order to analyze their behavior when subjected to pure abrasive wear. The tests were performed in a tribometer using diamond indenters of 200 ・m nominal tip radius to make scratches of 3 mm length, under linearly increasing loading from 1 to 18 N at 0.05 mm/s rate, for 60 s. The residual depth of the scratches was measured by profilometry. The results showed that, between the two morphologies of ZnO nanoparticles, fZnO has a greater capacity to reinforce PEEK, resulting in less scratching depth. HA did not disturb the reinforcement effect of fZnO. Moreover, the scratching of the cZnO-HA hybrid nanocomposite generated less friction, which is bad for the application, as it can cause the loosening of the implant. So, the fZnO-HA hybrid nanocomposite is a promising alternative when considering, for example, application in hip prosthesis stem, as this mixture can provide greater resistance to scratching and greater stem fixation within the bone.

e-mail: ccarrasco@yachaytech.edu.ec

To date the application of soft hydrogels to bone and cartilage regeneration is limited due to low mechanical modules (fracture and stiffness). To solve this, cryo(bio)printing surges as an alternative to improve the crystallinity of cross-linked hydrogels[1]. At same time, the lack of oxygenated bioprinted hydrogels construction can generate hypoxia inside hydrogelsand promotes cellular apoptosis. Oxygen supply for in vitro cell culture and in vivo 3D bioprinted structures is challenges to improve vascularization inside hydrogels structures. Ifcontrolled, oxygen levels must be maintained in many soft and hard Human tissues to promote the differentiation, viability, and proliferation of cells and in vitro/in vivo tissueformation. Although some technologies employ oxygen-generating materials to add sufficient oxygen levels, the limitations and challenges of current technologies include the lack of controlled, sustained, and prolonged release of oxygen. Herein, we disclose the engineering of oxygen-generating micro/nanoparticles in cells-laden GelMA hydrogels reinforced with nanofibers mats (more than three layers). GelMA displays tunable rheological and mechanical properties after addition of electrospun nanofibers mats (specialafter three layers), for sustained and prolonged oxygen-release. GelMA was cryo (bio)printing at a low temperature -20°C. Three groups were photo-crosslinked at 1, 5, and10 min, when the hydrogel constructions were cryo (bio)printing, by fluorescence microscopic analysis the results showed that highly ordered and parallel channels were evident, indicating a high specific surface area; therefore, smaller pore , lower degradation,and increased stiffness are reported in hydrogels at a lower temperature in comparison withGelMA hydrogels bioprinting room temperature. Our developed strategy demonstrated promising cell response within the high mechanical modulus engineered hydrogels constructions.

Influence of laser modification of the surface of a beta titanium alloy on its fatigue life

Leonardo Contri Campanelli[1], Diogo Alvarenga Garcia[1], ANA FLAVIA BEZERRA[1], Antonio Carlos Guastaldi[2], Danieli Aparecida Pereira Reis[1]

e-mail: leoccampa@hotmail.com

Laser technologies are known to provide significant improvements in the interaction between the substrate of a titanium implant and the bone tissue. The fact is that, as with any surface modification process, the laser can affect the fatigue behavior. This work compared the high cycle fatigue life of a commercial beta type titanium alloy, Ti-15Mo, with polished and Yb:YAG laser modified surfaces. Axial fatigue tests were performed under atmospheric conditions using a stress ratio of 0.1. The results revealed that for the employed process parameters, biologically promising according to the literature [1,2], the fatigue life of the beta type titanium alloy was affected by the laser modification. This follows a behavior similar to that of traditional titanium alloys and therefore requires great caution in the possible use of the laser as a surface modification process.

Influence of MgO on structural and spectroscopic properties of borophosphate bioactive glasses

Andrea Ferraz Silva Pereira[1], Marcelo Geronimo da Silva[1], Marcio José Barboza[1]

[1]Universidade Federal do Maranhão (*PPGCM*)

e-mail: andreafrrzs@gmail.com

Borophosphate glasses showed to be promising for medical applications, especially in the conformation of glass fibers, scaffolds and bioactive coatings of metallic implants for bone replacements [1,2]. This study aimed to analyze the structural and spectroscopic modifications caused by the addition of magnesium oxide in the system $40B_2O_3$-$25P_2O_5$-(20-x)Na_2O-$15CaF_2$-xMgO (x = 0, 2.5, 5, 7.5 and 10 mol%). The samples were synthed by melt-quenching method, characterized by volumetric density, molar volume, X-ray diffractometry (XRD), differential scanning calorimetry (DSC), Fourier transform infrared spectroscopy (FTIR) and tested in simulated body fluid (SBF) for 28 days to verify bioactivity. The formation of calcium phosphates (CaP) after SBF was investigated via FTIR analysis. XRD diffractograms confirmed the amorphous nature of the glasses. The increase in volumetric density and reduction in molar volume was observed for replacement of Na_2O by MgO. The DSC data showed increase in the glass transition temperature with the decrease in Na_2O/MgO ratio. FTIR spectra before SBF indicated structural changes in the glasses. Deconvoluted absorption bands of FTIR spectra suggest that the increasing of MgO caused depolymerization of vitreous matrix. However, the presence of MgO led to the formation of linear chains between forming species due to the crosslinks made by Mg^{2+} that are more stable than P-O-P, B-O-B and P-O-B linkages. FTIR spectra after SBF showed formation of CaP on all glasses. The results suggest that MgO increases the strength of bonds between the forming species of the samples. Finally, the glasses containing MgO are candidates for the manufacture of bioactive glass fibers.

Influence of surface charge to the hydroxyapatite deposition on titanium modified by calcium titanate.

Maria Gabriela Jacheto Carra[1], Júlia Bucci[1], João Ícaro Miranda Morais Garcia[1], Margarida Juri Saeki[1]

[1]Universidade Estadual Paulista (*Instituto de Biociências de Botucatu*)

e-mail: mg.carra@unesp.br

Ceramic materials based on calcium phosphate such as hydroxyapatite (HAp) play an important role in the biomineralization due to its similarity to the bone mineral matrix and, for this reason, they have been used as coatings for implant materials. However, one of the challenges is its low adherence to the metallic biomaterial such as titanium. To ensure a good bonding strength of the HAp, the titanium surface can previously be modified by chemical processes or coated with an intermediate layer [1]. The present work aims to coat titanium with calcium titanate and study the influence of surface charge (zeta potential) of substrates on the hydroxyapatite deposition. The deposition of calcium titanate films on commercially pure titanium (c.p.-Ti) was performed by the sol-gel method associated with dip coating technique, at a linear immersion rate of 5cm/min. It was then hydrolyzed under atmospheric humidity and temperature and finally, calcined at 400°C. The hydroxyapatite was prepared by the sol-gel method starting from $H_3PO_4$and $Ca(NO_3)_2$as alcoholic solution, deposited by immersion at 5cm/min and calcined at 700ºC. The samples were characterized using X-Ray Diffraction (XRD), Scanning Electron Microscopy (SEM), Energy Dispersion X-Ray Spectroscopy (EDX) and Surface Zeta Potential measurements. The analysis of zeta potential indicated that both, pure titanium and titanium coated with calcium titanate surfaces favor the adsorption of phosphates first and then the calcium adsorption, explaining the difficulty of apatite deposition from used sol. In addition, by determining isoelectric, it has been shown that the coatings favor the attraction of Ca^{2+}ions to the surface at physiological pH (7.4) and may contribute to the cell growth.

e-mail: joao.icaro@unesp.br

Calcium phosphate-based ceramics (apatites) are synthetic materials that have a chemical composition similar to bone tissue, which makes them interesting to use as biomaterials [1]. In this work, the apatite precursor sols at concentrations of 0.7 mol/L and 1.4 mol/L are prepared by dissolving calcium nitrate and phosphorus pentoxide in ethanol. The sols are kept at rest for 24 hours for hydrolysis (gelatinization) under room temperature and humidity. After hydrolysis, the resulting gels are dried at 80°C to remove the organic solvent and then calcined under different temperatures (from 500°C to 1200°C, with increments of 100°C) for 8h [2]. The X-ray diffraction analysis of the samples by the Rietveld method indicates that the samples are composed of monoclinic and hexagonal hydroxyapatite (HAp), the former being predominant, and calcium β-triphosphate (TCP)[3] .For the material started from the sol with a concentration of 0.7 mol/L, the hydroxyapatite fraction increases from 28.8% to 66.5% when the calcination temperature increases from 500°C to 800°C. Above this temperature, the fraction of this phase decreases. With a concentration of 1.4 mol/L, the hydroxyapatite fraction decreases from 88.2% to 19.5% progressively with increasing temperature from 500°C to 1200°C. The micrographs revealed the formation of particulate but porous materials that agglomerate without sintering up to a temperature of 900°C, from where the formation of sintered and dense agglomerates is observed. The results of the EDX analysis showed a Ca/P molar ratio ofaround 1.5 for all materials. The cytotoxicity assay, using pre-osteoblast cells (MC3T3-E1,Subclone 4) by non-direct contact of 24h, showed that cell viability and adhesion did notdiffer from those of the control. A decrease in viability and adhesion was observed for samples prepared at a concentration of 0.7 mol/L and calcined at temperatures above 900°C.

Inhibition of biofilm formation on titanium surfaces by non-thermal atmospheric plasma jet

Jussier de Oliveira Vitoriano[1,2], Gabriel de Moura Martins[2], Patrícia Pimentel de Barros[2], Carlos Eduardo Bezerra de Moura[1], Caio Sérgio Santos[1], Janine Karla França da Silva Braz[2], Carlos Augusto Galvão Barboza[2], Clodomiro Alves Junior[1,2]

e-mail: ssier_6@hotmail.com

The aim of this in vitro study was to evaluate the antimicrobial efficacy of a non-thermal atmospheric plasma jet in inhibiting biofilm formation. Biofilms can cause serious infections and compromise the functioning of implants or injured tissues. The irreversible adhesion of bacteria is the first step of biofilm formation and can be prevented by methods that control and inhibit this adhesion. The atmospheric plasma jet is a promising method, as it is safe, easy to apply in physically complex environments and not prone to microbial resistance [1, 2]. However, there are still a lack of relevant standards for the clinical application of plasma devices, which stimulates the growth of research and studies in the area. In this study, titanium surfaces were exposed to an argon plasma jet and analyzed for their wettability and biofilm formation by Pseudomonas aeruginosa in 24-well plates for 48h. The plasma treatment significantly changed the hydrophilicity and chemistry of the treated titanium surface. The mature biofilms of P. aeruginosa formed on the treated surface showed a reduction of 92.32% (p=0.0001) in the viable cell count (CFU/mL) compared to the untreated control. These results are discussed in light of the reactive nitrogen and oxygen species (RONS) present in the plasma and their influence on the formation of functional groups on the treated surface. In conclusion, our study demonstrated that the argon plasma jet can alter titanium wettability and inhibit biofilm formation.

Investigation of multi-element-doped mesoporousbioactive glass by multi-technical spectroscopic approach

Gabriela Colares Ali Ganem[1], João Henrique Lopes[2]

[1]Instituto Tecnológico de Aeronáutica (*Departamento de Química*) , [2]Instituto Tecnológico de Aeronáutica (*Departamento de química*)

e-mail: gabrielacganem@gmail.com

Bioactive glasses (BGs) have been investigated for numerous tissue engineering applications, as multifunctional delivery systems for a variety of therapies, from bioinorganic species to biomolecules (e.g., drugs, growth factors, DNA, contrast agents for diagnostic imaging) [1]. Several studies confirm that bioinorganic species incorporated into the glass composition stimulate important biological activities through ion-mediated therapy and, moreover, are crucial for the formation of the glass network and influence the glassy microstructure and thus the bioactivity of the BGs [1]. The incorporation of biologically active species such as boron, copper, and zinc into bioactive glass compositions has resulted in biomaterials with high bioactivity, interesting antibacterial properties, and stimulation of osteogenesis, angiogenesis, and immunomodulation for tissue regeneration [2]. In this work, we report the synthesis and characterization of multi-elemental glassy compositions derived from the SiO2-CaO-B2O3-ZnO-CuO system. An innovative sol-gel method was used to obtain glasses with high structural homogeneity. The SEM data show that the bioactive glasses have a spherical morphology, while the N2 adsorption-desorption isotherm indicates a mesoporous structure with a high specific surface area for all the studied glasses. The chemical composition of the glasses was confirmed by elemental analysis, yielding values close to nominal. Due to morphological and physicochemical properties, multielement bioactive glasses show great potential as bioactive fillers or drug delivery systems in a variety of applications including bone regeneration and wound healing.

Hydroxyapatite (HAP) is a Calcium Phosphate whose crystal structure is similar to bone tissue and is widely used for bone implant coating due to its high biocompatibility and osteoconductivity [1]. Such application demands a crystalline material with the correct stoichiometry of HAP. Heretofore, these conditions have been achieved only with heat treatment, which introduces problems and limitations to the technique. We present and explain the mechanisms to control the crystallinity at room temperature through parameter tuning.

Nd:YAG (532nm) Pulsed Laser Deposition has produced crystalline HAP coatings at room temperature [2], the present work investigates the effects of laser fluence, pulse frequency and pressure on crystallinity.

The effects of the tuning on the crystal structure were determined through Grazing Incidence x-Ray Diffraction, the chemical properties and stoichiometry were measured by x-Ray Photoelectron Spectroscopy.

It is hypothesized that there is a thermal and kinetic energy transfer from the ablated material to the subtract such that room temperature crystallinity is achieved. The kinetic energy of the plasma plume has been determined through Time of Flight type measurements as a function of the different parameters.

The results suggest that the main mechanism is not a kinetic energy transfer, given that it didn’t vary when the pulse frequency was changed, but a difference in crystallinity was observed. Also, as the pressure raised and the kinetic energy lowered, no change in crystallinity was noticeable.

Therefore, another mechanism is responsible for transferring the necessary energy for the crystallization, it is proposed to be thermal. A new experimental setup is being developed for thermal measurements and further investigation.

Borate glasses can be completely converted to hydroxyapatite (HA) and present a higher rate of ion release when immersed in physiological fluids compared to silicates [1]. Metal ions, as Zn2+, can be added to borate glasses to improve their bioactive properties, once this ion has feature of stimulating osteogenesis, wound healing and antibacterial action [2]. In this research, vitreous samples containing ZnO with concentration of 0-10 mol% ((64-x)B_2O_3-2P_2O_5-18 CaO-16Na_2O-xZnO, x= 0, 1, 2.5, 5, 7.5 e 10 mol %)) were synthesized inorder to confirm bioactivity and potential for application in the hard and soft tissues regeneration. The glasses were immersed in Simulated Body Fluid (SBF) for 7, 14, 21 and 28 days to observe the growth of a HA layer on their surfaces in order to attest their bioactivity. The verification of the HA layer was performed by X-ray diffraction analysis (XRD), Fourier transform infrared spectroscopy (FTIR) and daily pH measurement of SBF in which the samples were immersed. XRD, FTIR and cytotoxicity analyzes were also performed before soaking in SBF. Cytotoxicity analysis indicated that all samples are non-toxic, showing no decrease in cellular viability of RAW-47 macrophages. The appearance of characteristic peaks and bands in the DRX analysis and FTIR spectra, respectively, confirmed the formation of HA layer attesting the tissue binding potential of the prepared materials.This study was partly financed by Coordenação de Aperfeiçoamento de Pessoal deNível Superior - Brasil (CAPES) - Finance Code 001. TiO_2nanotubes (TNTs) are oxide films grown over Ti substrates via electrochemical anodization in the presence of fluoride ions. TNTs have potential biomedical applications, such as covering implants for bone tissue restoration. Despite the widespread use of Ti-6Al-4V (Ti64) alloys in medical implants due to their bioinert capacity, long-term complications can lead to biological malfunctions. This work aims to investigate the growth, mechanical, and compositional properties of TNTs grown over Ti64 substrates, focusing on biomedical applications. After anodization, characterizations indicated promising results, with well-ordered nanotube formation observed by SEM, and the presence of an initial porous layer on the surface, likely associated with the initial phase of tube formation in organic electrolyte solutions. Mechanical characterization revealed an almost constant elastic modulus for low penetration depth of 24 GPa, indicating the major influence of substrate and densification components on these properties. XPS analysis showed variability in oxide compositions with increasing film depth, possibly attributed to defects in the crystal lattice due to oxide formation. Moreover, the dominance of TiO_2in the films was attributed to the initial surface nanometers, likely correlated with the initial porous layer, which did not form other oxide compositions, possibly due to the smooth formation process during the initial anodization phase that did not introduce defects into the lattice. After annealing at 450ºC for 1.5h, anatase crystal structure was obtained, exhibiting improved properties for biomedical applications.

The design of hydrogels that produce oxygen in a controlled manner may offer a unique solution to prevent ischemia-induced death of implanted cells. It indicates oxygen generating hydrogels have the potential to improve tissue engineering strategies that aim to regenerate ischemic tissues. Herein for the first time calcium peroxide (CPO) was laden into Laponite (LAP) hydrogel at different concentrations and evaluated bactericidal effect. The oxygen releasing was measured in hypoxic conditions with control of temperature. After 5h, the concentration decreased to 29.0% for Laponite-CPO (20.0%). However, during the first 5h, Laponite-CPO hydrogels showed increase of oxygen release. The antimicrobial activity is improved significantly with the addition of Laponite to gram-positive and gram-negative microorganisms, improving antibacterial barrier properties. The highest averages in the of the inhibition halos produced by the hydrogels were obtained at concentrations of 5% and 10%. However, it was possible to observe halo reduction, in the highest concentration of CPO. The discs probably adsorbed CaO2, making it difficult to release to the medium. To conclude, Laponite-CPO hydrogels presented antimicrobial activities being a potential candidate for the treatment of infections and consequent helping the healing of skin wounds.

Biocatalysts based on enzymes immobilized on supports have the potential to produce materials with great catalytic efficiency and the reactions can be conducted under mild conditions. In this work, new magnetic support for the immobilization of the lipase enzyme from Thermomyces lanuginosus (TLL) was proposed. A mesoporous and magnetic material was obtained by the sol-gel method in the presence of natural magnetite particles extracted from a Brazilian mine. The synthesis procedure uses eco-friendly concepts since no previous harmful to the environment magnetite synthesis was required. The magnetic xerogel (MX) was modified with gold nanoparticles stabilized by chitosan (MX-Au) and subsequently, TLL enzyme was immobilized on the surface of both materials, to produce MX/TLL and MX-Au/TLL, respectively. The materials were characterized by X-ray diffraction, N2 adsorption-desorption isotherms, thermogravimetric analysis and magnetism. The gold nanoparticles dispersion was characterized by UV-Vis spectroscopy and Transmission Electron Microscopy. The results indicate 5.5 ± 1.6 nm for AuNp diameter, the supports are mesoporous, magnetic and the amount of immobilized enzyme is similar in both materials. The enzymatic activity was evaluated by using the p-nitrophenillpalmitate hydrolysis (colorimetric method). The immobilization parameters were optimized by applying a two-level factorial design which led to the immobilization time of 15 h and pH 5.0. In these conditions, about 66 and 97 % of immobilization yield is obtained for MX/TLL and MX-Au/TLL. Also, the biocatalysts can be reutilized. After 12 cycles, the MX/TLL and MX-Au/TLL biocatalysts preserved 30 and 45% of the initial activity. Moreover, the MX-Au/TLL biocatalyst can be stocked for four months without activity loss. Therefore, the magnetic materials with a planned porous structure and easy synthesis developed in this work have potential application as easy-recoverable and recyclable biocatalysts.

MATRIX VESICLE-EMBEDDED COLLAGEN SCAFFOLDS FOR INVESTIGATING BONE MINERALIZATION

e-mail: maryannem@usp.br

Bone mineralization is a highly orchestrated and dynamic process that has been studied from a structural, chemical, and biological point-of-view.1The bone tissue can be described by the action of mineralization-competent cells embedded in an extracellular matrix composed mainly by collagen.1,2Those cells release a special class of extracellular vesicles, named matrix vesicles (MVs) which are the responsible for the deposition of an inorganic phase called biological apatite on collagen fibrils.2Thus, the fabrication of 3D-collagen scaffolds embedded with MVs offers alternative strategies to investigate bone mineralization in order to contribute for the development of cell-free therapies. Here, self-assembled 3D-matrices were obtained from the exposure of high concentrated type I collagen solutions to NH3(g) for 24 hours, replicating the microenvironment of the native tissue. MVs were isolated from a pre-osteoblastic (MC3T3) and vascular smooth muscle cell line (MOVAS) cultivated in osteogenic medium. The average mean diameter of both the vesicles was 105 + 19 nm, as determined by nanoparticles tracking analysis. The specific activity of TNAP was 7.5 and 1.2 + 0.6 U.mg-1 for MVs from MCT3T3 and MOVAS respectively, confirming their mineralizing potential. FTIR spectroscopy confirmed the formation of apatite after immersion of the vesicles in synthetic cartilage lymph. Morphological and spectroscopic analysis, revealed the ability of MVs to bind to the collagen scaffolds and propagate the mineral formation from the addition of ATP, simulating the process observed in vivo. Thus, reproducing the organization of collagen fibrils embedded with MVs in vitro is a suitable method to design mimetic models to study (patho)physiological mineralization processes. Abstract:
Orthopedic prostheses combine biocompatibility factors with mechanical properties of the constituent materials. In this perspective, the response induced by Young modulus of the material through the femoral bone and prosthesis are found in the phenomenon of bone remodeling. Studies from the last two decades, controlling alloys phases, denote the management of β phase associated with precipitation of α phase as a promising technique to obtain high mechanical strength with the necessary ductility of biomaterials. Thus, the aim of this study was to evaluate the adequacy of stress distribution of different titanium alloys in view of requests from the orthopedic sector, based on the validations present in computationalsimulations of finite elements to determine possible applications of these alloys in femoral prostheses. From the values obtained with the follow-up of the result regarding the maximum Von Mises tension (σVM) of the healthy femoral bone and the average Von Mises tension (σVM) of the prostheses, it was possible to correlate the stimulus to bone remodeling (ξ), and so the alloy with best performance was Ti-26Nb-4Zr-3Mn.

Keywords: β titanium, femoral prostheses, finite element method.

Introduction

The biomaterials composition demands mechanical resistance in cyclic and repetitive movements, manifested by multiaxial loads [1]. Those requirements are met by titanium alloys, with a young modulus of 110 GPa [2]. The Ti-6Al-4V alloy has the best cost on the market, but it is limited in terms of toxicity, caused by the presence of vanadium and the tendency of aluminum to promote neurological diseases [1]. Another factor that limits the application of this alloy in biomaterials is the progression of conditions resulting from oxidative stress in orthopedic implants [3].

The finite element method tool, illustrated in Figure 1 (l), makes it possible to determine the bone remodeling factor (ξ), which corresponds to the ratio of deformation energy caused by the prosthesis implanted in the femur in relation to the healthy femur, shownin Figure 2 (a), through the mobility of effect meshes by nodes in the three-dimensional geometries of the bodies [1]. This parameter, which is ideal when approximated to the value of “01” for periprosthetic bone nodes, corresponds to a real distribution of stress in healthy bone. In this way, it is possible to obtain the corresponding mobility alloy with betterperformance for femoral prostheses against stress shielding [1]. The purpose of this work was to evaluate the real feasibility of using commercial β-type titanium alloys on hip implants, bya computational tool, based on their mechanical properties.

Experimental Procedure (or Computational Procedure)

The titanium alloys in this work are $\alpha+\beta$ type, including the versatile Ti-6Al-4V alloy, illustrated in Figure 2 (b), conventionally applied in prostheses for THA surgery, in addition to the β-type alloys, namely and shown in Figure 2: Ti-13Nb-13Zr (c), Ti-12Mo-6Zr-2Fe (d), Ti-15Mo (e), Ti-16Nb-10Hf (f), Ti-15Mo-5Zr-3Al(g), Ti-35Nb-7Zr-5Ta (h), Ti-29Nb-4,6Zr-13Ta (i), Ti-26Nb-4Zr-3Mn (j), Ti-35Nb-2Ta-3Zr (k) [1] [2].

Finite element simulations were performed using the ANSYS Student 2022 R1®software, in static structure analysis. The beginning of the modeling of the periprosthetic system started with the use of three-dimensional geometries corresponding to a left femoral bone measuring 416mm in length and an orthopedic prosthesis with a head measuring 36mm in diameter, both widely used and available in open libraries [1]. The manipulation of the software geometries was performed with the attachment of the solid referring to the orthopedic prosthesis, shown in Figure 1(l). Then, the two three-dimensional geometries were unified, in fixation by contact between 3 faces of each geometry, which make up the periprosthetic system, illustrated in Figure 1 (m) and (n). Meshes referring to the junction of discrete nodes were generated and adjusted. In the geometry model section, the lower support was fixed to the bone geometry, at the distal end of the femur, illustrated in Figure 1 (o) and (p), followed by the application of loads analogous to the action of walking [2], which generate a resultant force of 3231.4 N and a reaction of the greater trochanter group of the bone at 1085.2 N.

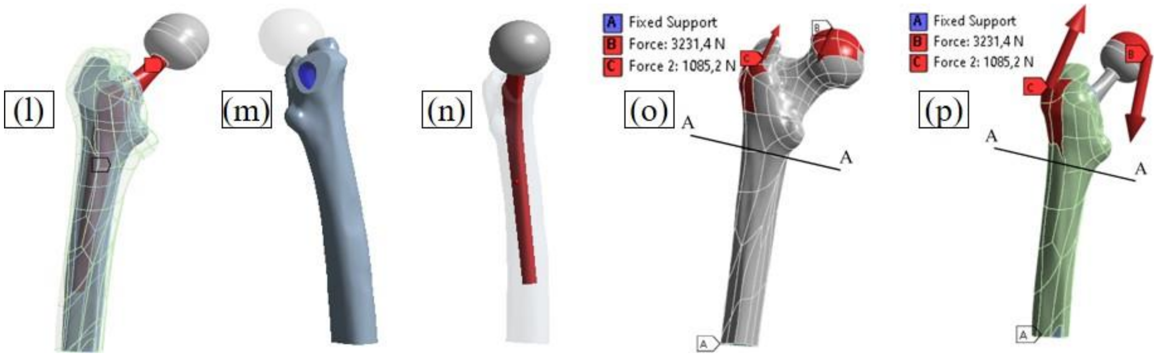

Figure 1: Geometries (l) Fragmentation of hip and periprosthetic system; (m) Medullary system contacts; (n) Femoral prosthesis contact faces. Loads on the greater trochanter and hiphead related to the act of walking. (o) Healthy Bone; (p) Peripsthetic system.

To obtain the bone remodeling factor of each titanium alloy, Image J Software was used to compare the scalar components proportional to the strain energy of each geometry [1].Thus, the Von Mises stress record of the cortical layer of the periprosthetic bone ($VM_{Periprosthetic}$), from the pixel analysis of the A-A section, was divided by the Von Mises stress of the healthy bone ($VM_{Healthy\ Bone}$) of the same A-A section.

Results and Discussion

From the maximum Von Mises stress (σVM) generated in the simulation and the boneremodeling factor ξ, a low or null variation of stresses in the medullary region of the femoral bone in both systems can be observed, shown presented or shown in Figure 2, in the order of7 MPa, illustrated with a blue spectrum. In contrast, there is greater stress dispersion in the cortical region of periprosthetic sections compared to the cortical region of healthy bone, a factor responsible for demonstrating the stress shielding phenomenon, as already expectedand described in the literature [1]. The anteromedial region presented requests to tensions in the average order of 40 MPa. Thus, the Ti-26Nb-4Zr-3Mn alloy, with the lowest elastic modulus (32 GPa), was the material that showed the lowest stress concentration in the critical section A-A, with a maximum of 42.14 MPa and a higher ξ factor of 0.482. It represents the titanium alloy with the best performance, due to its proximity to the elastic modulus of the femoral bone. Conversely, the conventional Ti-6Al-4V alloy showed the highest stress concentration in the critical section A-A, with a maximum of 104.33 MPa and a ξ factor of 0.353, being 36.54% more capable of causing bone remodeling, when compared to theTi-26Nb-4Zr-3Mn alloy.

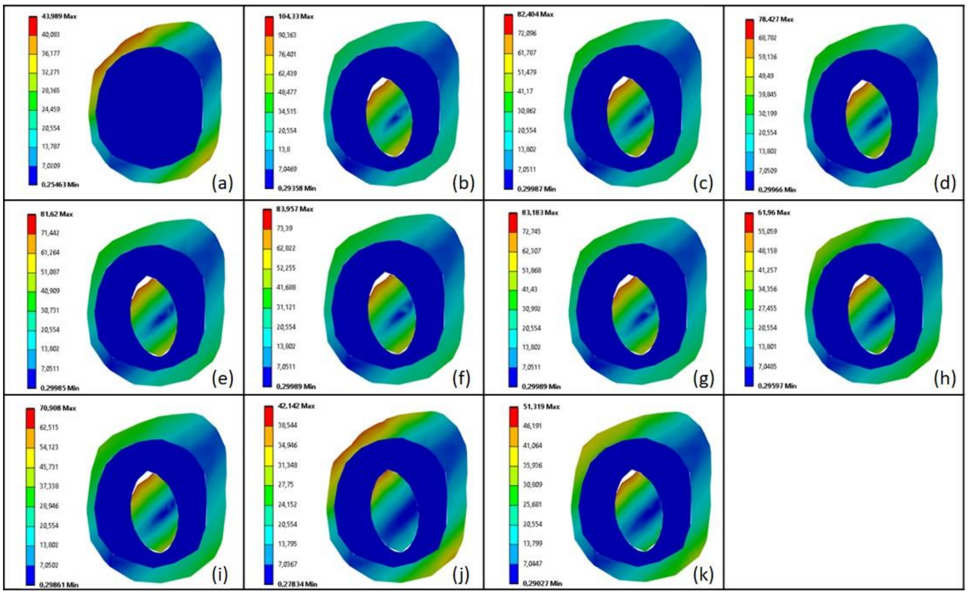

Figure 2: Von Mises stresses distributed in the proximal region of the femur (section A-A).

Conclusions

The computational finite element simulations demarcated the mechanical properties of titanium alloys in relation to periprosthetic bone geometries. The Ti-26Nb-4Zr-3Mn alloy obtained the best performance. The simulations were marked by the low number of simulationnodes and uneven distribution of meshes that limited the accuracy of obtaining the bone remodeling factor. This event should be investigated in future studies.

Mechanical properties and degradation rate of a synthetic bipartite sling modified with a biocompatible and elastomeric midline segment for the correction of stress urinary incontinence

Vinícius Oliveira[1], Márcia Cristina Branciforti[2]

[1]University of São Paulo (*Materials Engineering*) , [2]University of São Paulo (*Department of Materials Engineering*)

e-mail: vinicius_oliveira@usp.br

Urethral suspension surgery combined with the use of synthetic porous tapes (sling) is a worldwide standard and effective procedure for curing stress urinary incontinence (SUI) [1]. However, the force exerted by the sling shortens the urethral canal and causes postoperative urinary retention [2]. In order to avoid the requirement for a second surgical intervention in these patients, a patent was developed in 2010 about a bipartite polypropylene sling interconnected by a small midline segment manufactured from a unspecified biodegradable material that relieves stress over the organ and clears the flow of urine. In this work we evaluated the behavior of a biodegradable poly (glycerol sebacate) elastomer (PGS) used as a midline connection of the bipartite sling and the physicochemical properties of the elastomer. Bipartite slings were made from PGS obtained at different cure times and evaluated for their adhesion strength after in vitro degradation for 7, 14, 21 and 45 days. The PGS elastomer manufactured to be used in slings, were evaluated by infrared spectroscopy (FTIR) and the measurement of swelling percentage and density. The PGS analyzes applied to the slings indicate better crosslinking for 72 hours sample, as well as better performance of mechanical properties over 45 days of degradation. This study pointed out that this polymer obtained by curing for 48 to 72 hours is suitable for use as midline segment of the bipartite slings, although it needs additional in vitro/in vivo studies for specific definition of cure time.

Strategies for the production of new nanocomposites that promote bone tissue regeneration are important, especially those that potentiate hydroxyapatite osteoinduction in situ [1]. Here, we study the synthesis of nanohydroxyapatite and Titanate (nHAp/TiNT) formulated at different concentrations (1, 2, 3 and 10% dye mass) by means of a wet aqueous chemical reaction. The crystallinity index (CI) calculated by Raman and XRD spectroscopy showed that the values decreased as the tonality concentration increased, which confirmed its addition to the nanocomposite structure. The SEM images showed the presence of shades in the Nanocomposite. The in vitro study, bioactivity assays (SBF 5x), showed the nanocomposites reactivity by increasing the SBF solution's pH after the periods of 7º and14º days and the values calculated for the carbonate content increased with the immersiontime, indicating the presence of carbonated Hap. We also verified the cytotoxicity of the cellline of murine fibroblasts L929, revealing that there was no remarkable cell death in any ofthe concentrations tested. In vivo regenerative activity was performed in models of oophoromized animals (rats) organized into seven groups containing five animals each, in two experimental periods (15 and 30 days), occurring bone regeneration in all groups tested in 30 days. However, the nHAp/TiNT10% group presented statistically higher tissue repair compared to the untreated control group. Thus, the results of this study are promising for numerous applications in bone tissue regeneration.

NEW STRATEGY FOR TREATING TUBERCULOSIS: OBTAINING STRUCTURAL, VIBRATIONAL, AND THERMAL STUDIES OF ISONIAZID SALT-TYPE SOLID DISPERSION

Raychimam Douglas Santana Bezerra[1], Ayslla Campos Moura[1], Paulo Roberto da Silva Ribeiro[1]

[1]Universidade Federal do Maranhão

e-mail: raychiman.d@gmail.com

Isoniazid (ISO) is an antibiotic for treating bacterial diseases like tuberculosis. It belongs to the biopharmaceutics classification system class III drug and is unrelated to water solubility problems. However, it presents stability problems in fixed-dose combinations (FDC), commonly used in treating tuberculosis. Solid dispersions of drugs (SDs) such as salts have been an alternative to overcome this problem. Considering this information, this study aimed to obtain and characterize an ISO salt with acetylsalicylic acid (ASA). This salt wasobtained by slow solvent evaporation (SLS) in a molar ratio of 1:3 (drug: drug). Subsequently, the ISO-AAS salt (1:3) was characterized by X-ray powder diffraction (XRD), Fourier transform infrared spectroscopy (FT-IR) and Thermogravimetry (TG), Derivative Thermogravimetry (DTG) and Differential Thermal Analysis (DTA). The XRD results showed that the ISO-AAS salt (1:3) exhibited a new crystalline phase and had new crystallographic peaks at 6.0°, 11.5°, 16.3°, 17.9°, 19.2°, 21.2°, and 28.0° 2(θ), indicating an interaction between ISO and AAS. FT-IR spectrum proved the interaction between the two substancesoccurring through the primary amine of ISO (-NH2) and the carboxyl group of AAS, evidenced by vibration at 1500 cm-1 in the ISO-AAS salt spectrum (1:3) referring to the formation of the carboxylate (COO-). Finally, the DTA curve showed an endotherm for melting this salt at 92.6 °C (Tonset). This temperature is lower than the meltingtemperatures of the starting compounds, indicating that ISO-AAS (1:3) will favor an increase in water solubility, bioavailability, and therapeutic efficacy of ISO, supporting the production of more effective drugs in the treatment of tuberculosis.

OBTATION AND SPECTROSCOPIC CHARACTERIZATION OF SOLID DISPERSIONS OF THE ANTIHYPERTENSIVE CANDERSATAN CILEXATIL

Ayslla Campos Moura[1], Paulo Roberto da Silva Ribeiro[1]

[1]Universidade Federal do Maranhão

e-mail: ayslla.moura@discente.ufma.br

Candesartan cilexetil (CAN) is a medicine used in the treatment of systemic arterial hypertension. It belongs to Class II of the Biopharmaceutical Classification System, presenting low water solubility, contributing to the reduction of its bioavailability and therapeutic efficacy. Obtation solid drug dispersions (DSFs) has become an alternative for improving the physicochemical properties of poorly soluble drugs. This work aimed to obtain and characterize CAN DSFs with tromethamine (TRIS), using slow solvent evaporation (SEL) methanol. After obtaining the CAN-TRIS DSFs, they were characterized by powder X-ray diffraction (XRD) and by Fourier transform infrared spectroscopy (FT-IR). A study of the physical stability of these DSFs as a function of time using the DRXP was also carried out. Difractograms of CAN-TRIS binary mixtures in molar ratios of 1.5:1.0; 1.0:1.0; 1.0:1.5 and 1.0:2.0 were typical of amorphous materials, as they did not show crystallographic peaks. Thus, there is evidence of intermolecular interactions between the starting compounds, resulting in the formation of co-amorphous DSFs. CAN-TRIS co-amorphous (1.5:1.0); (1.0:1.0); (1.0:1.5) and (1.0:2.0) showed good physical stability for up to 168, 365, 308 and 21 days, respectively. The FT-IR spectra of these DSFs confirmed the occurrence of these interactions between the carbonyl and amine groups of CAN and the amino and hydroxyl groups of TRIS. Assuming that amorphous materials are more water soluble than crystalline materials, the CAN-TRIS co-amorphous obtained in this work will contribute to increase the CAN dissolution rates and its bioavailability. Thus, these materials are very attractive for the production of more effective drugs for the treatment of hypertension, as well as for reducing the side effects of this medicine.

Particle size decrease of titanate nanotube by using lyophilization technique

Leticia Terumi Kito[1], Angélica Galvão dos Santos Silva[2], Tiago Moreira Bastos Campos[3,4], Gilmar Patrocínio Thim[5]

e-mail: leticiakito18@gmail.com

Materials on a nanoscale have recently received attention due to the search for materials that can be easily manipulated to improve their properties. Among them, titanate nanotubes (TiNT) have received greater attention due to their photocatalytic properties, cost-effectiveness, large surface area, high chemical stability, antimicrobial action, and biocompatibility. However, a challenge encountered is their natural tendency to agglomerate, which reduces their effectiveness. Therefore, this study aimed to analyze the morphological differences between TiNT and lyophilized TiNT. Lyophilization seeks to reduce the agglomeration since the conventional drying process can induce nanoparticle stresses that favor the aggregation. Titanate nanotubes were obtained via hydrothermal synthesis, with one part being dried at 60 °C for 24 hours (sample TiNT) and the other part dispersed in deionized water for 3 minutes using an ultrasonic probe and then frozen at -10 ºC. After that, the sample was placed in a lyophilizer for 3 days at -100 °C under a pressureof 200 μHg (sample TiNT_L). The system’s low pressure promotes solvent sublimation and prevents the particle aggregation. Morphological changes were evaluated by scanning electron microscopy (FEG-SEM), X-ray diffraction (XRD), infrared spectroscopy (FT-IR), and dynamic light scattering (DLS). XRD and FT-IR results indicated no significant alterations in the physicochemical properties of the samples. However, the DLS results showed that the sample TiNT_L exhibited an average particle of 103.2 nm, while the TiNT sample had a particle of 265.5 nm. Furthermore, the FEG-SEM showed that the TiNT_L sample exhibited increased porosity which is a promising outcome for photocatalytic activity and suitable for biological applications.

Mercaptopurine (6-mercaptopurine or 6-MP) treats cancer, particularly leukemia. Common side effects of mercaptopurine include nausea, vomiting, loss of appetite, and increased risk of infection due to immune system suppression. The technology of controlled release of drugs can potentially overpass many problems related to the traditional administration ofactive principles by regulating the rate and spatial localization of the released agent. [1]-[5] Polycaprolactone (PCL) is a biodegradable polyester used in medical applications such as drug delivery and tissue engineering. [6] Chitosan (Chi) is a cationic polysaccharide biocompatible. [7] In this work a doble layer device composed of PCL and Chi/6-MP ‘s were produce using solvent casting and compression molding. The PCL/Chi/6-MP films were characterized by SEM, the results show a multilayer material with modifications on 6-MP's morphology and thickness of approximately 0,25mm. Furthermore, studies will be carried out to evaluate the release of 6-MP.

Several scientists and biomaterials engineers have studied phenanthroline coordination compounds involving divalent and trivalent metal ions due to the cytotoxic effect and selectivity that these materials present in various cancer cells [1, 2]. Motivated by this context, here we report the synthesis of two cytotoxic complexes based on 1,10-phenanthroline-magnesium sulfate heptahydrate $[Mg(H_2O)_3(phen)(SO4)]$ and 1,10-phenanthroline-neodymium nitrate hexahydrate $[Nd(Phen)_2(NO_3)_3]$ from the slow evaporation method. Furthermore, the structural, vibrational, thermal, and electronic properties were characterized and discussed. Computational studies based on density functional theory (DFT), Hirshfeld surfaces, and crystal voids supported the experimental analyses. Complementarily, a cytotoxic assay was performed on two cancer cell lines MCF-7 and SiHa, and a healthy cell line GM07492A. The obtained data showed that both complexes crystallized in monoclinic symmetry but with distinct spatial groups. Infrared vibrational spectra presented the main functional groups and exhibited a good correlation to the theoretical DFT results. In addition, considerable thermal stability and electronic dielectric gap were observed for the crystals. From the Hirshfeld surfaces and the lattice voids, it was possible to estimate the intermolecular interactions and unit cell free spaces qualitatively and quantitatively. Finally, the samples showed excellent cytotoxic activity against cancercells and showed higher levels of selectivity for the MCF-7 tumor cell line.

e-mail: guilherme.guerini@unifesp.br

Copper (Cu) and its alloys have attracted the attention of researchers in recent years due to their natural and microbicidal capacity against various microorganisms for several applications in medicine and as a way to prevent the spread of diseases in environments with high human circulation (hospitals and public transport) [1]. However, the use of pure copper is impaired by the process of oxidation and corrosion that affect the aesthetics and useful life of the material. Thus, the present study evaluated six CuZnNi alloys in order to understand its physicochemical characteristics and microbiological activity against Escherichia coli and Staphylococcus aureus. Cyclic voltammetry, open-circuit potential measurements and potentiodynamic tests were carried out in NaCl 0,5 M in order to determine the corrosion behavior followed by bacterial recovery and plating tests to verify the microbicidal activity using stainless steel 304 as positive control. X-ray diffraction (XRD), optical microscopy, and scanning electron microscopy (SEM) were used to characterize the alloy surface and their corrosion products. The results showed that the Cu68,85Zn26,36Ni4,69 alloy presented the best corrosion behavior (Ecorr= -194 mV and icorr= 1.07 µA.cm-2) compared to other alloys for the same biological activity that promoted full inactivation within 1h of contact with the alloy surface. Furthermore, the addition of Ni promoted a refinement in the dendritic microstructure confirmed by optical microscopy and XRD data confirmed an α-phase crystalline structure. In conclusion, as all alloys obtained the same microbicidal results, the chosen alloy demonstrated better physicochemical properties and could become an alternative for future medical and sanitary applications.

Metal orthopedic and dental implants are widely used for the fixation and replacement of bone tissues. Biomaterials researchers have focused their efforts on developing strategies to minimize implant-associated failures, for example, by surface modification of metal alloys with multifunctional coatings [1]. In this context, poly (methyl methacrylate) (PMMA)-silica hybrid coatings have shown to be very promising for improving the bioactivity, biocompatibility, and corrosion protection of Ti6Al4V alloy [2]. This study focuses on the preparation of multifunctional PMMA-silica coatings modified with hydroxyapatite (HA), β-tricalcium phosphate (β-TCP), and cerium oxide (CeO_2) nanoparticles with bioactive and antibacterial properties. CeO_2 was synthesized by the hydroxide-mediated precipitation method. PMMA-silica hybrids modified with HA, β-TCP, and CeO_2 were obtained by covalently coupling the polymeric phase of methyl methacrylate (MMA) and 3-methacryloxypropyl trimethoxysilane (MPTS) with the silica nanophase, synthesized by sol-gel reactions of tetraethylorthosilicate (TEOS). The 17 μm-thick coatings deposited by immersion on Ti6Al4V are homogeneous and show a strong adhesion (>12 MPa). X-ray diffraction (XRD) and atomic force microscopy showed that the CeO_2 particles have a cerianite structure and sizes in the range of 40–100 nm. The effect of HA, β-TCP, and CeO_2 on the structural properties was evaluated by infrared spectroscopy, XRD, thermal analysis, and contact angle measurements. The corrosion efficiency was studied by electrochemical impedance spectroscopy in a simulated body fluid (SBF) solution. The modified coatings showed an impedance modulus of up to 74 GΩ cm^2, which remains 3 decades higher than the uncoated Ti6A4V alloy after 49 days of exposure to SBF.

The search for new alternative antimicrobial formulations to antibiotics has grown over time in view of increasing resistance to conventional antimicrobials. In this way, the copper ion has shown a broad spectrum antimicrobial action against bacteria, fungi and viruses [1]. In this study, nanogels based on polyetheramine and epoxide [2] were obtained using water as aqueous medium. For this purpose, a polyetheramine (based on propylene oxide PPO) and diepoxy PEG were "click" to obtain the polymeric nanogels. The influence of Cu ions amounton antibacterial properties was evaluated. The nanogels were physicochemical characterized by different techniques such as Dynamic Light Scanning (DLS), zeta potential, Transmission Electron Microscopy (TEM). For biological tests, the minimal inhibitory concentration (MIC) technique was used for the antimicrobial tests and the XTT cell viability assay for the cytotoxicity test. Zeta potential measurements of the pure nanogels revealed ζ-potential of 5±1 mV and from the TEM micrographs was observed spherical morphology of the nanoparticles. The nanogels exhibited antibacterial activity against both Gram-negative and Gram-positive bacteria, which was further enhanced by adding copper ions at low concentrations. Additionally, the nanogels undergo enlargement from 380 to 500 nm with temperature and storage time, while the incorporation of copper does not significantly affect this behavior. These nanogels will be crucial in designing new functional nanomaterials for biomedical applications.

Polymer-Based Injectable Nanocomposites Containing Silica Particles for Targeted Delivery of Hydrophilic and Hydrophobic Drugs

Lucas da Silva Ribeiro[1], Renata Lang Sala[2], Arthur Martins Gabriel[1], Fernanda Milanez Brugnari[1], Emerson Rodrigues de Camargo[1]

[1]Universidade Federal de São Carlos (*Departamento de Química*) , [2]University of Cambridge

e-mail: lucas.ribeiro@estudante.ufscar.br

Despite all the advances in the pharmaceutical area, there is still some problems to be overcome, such as the rapid degradation of amino acids and proteins after administration and the controlled release of hydrophobic drugs due to their low solubility, which results in low bioavailability of these compounds [1]. Thus, this study focused on developing localized drug delivery systems for protection and improved efficacy of drugs, using thermoresponsive polymers that undergo a sol-gel transition at physiological temperature. Nanocomposites based on poly(N-vinylcaprolactam) and silica particles were synthed as drug carriers for hydrophobic and hydrophilic drugs [2]. Rheological analysis showed that the nanocomposites can be locally injected to target sites, and the addition of silica nanoparticles minimized premature material dissolution and rapid drug release. The synthed polymers sustained a controlled release of drugs for 7 days under physiological conditions. Kinetic analysis showed that the release of naringin is controlled by diffusion, while the release of doxorubicin is controlled by anomalous transport. A preliminary in vitro study showed negligible toxic effects on healthy cells and better efficient inhibition of carcinoma cells. The study shows that it is possible to use injectable PNVCL-based thermosensitive nanocomposites with silica nanospheres for both hydrophilic and hydrophobic drug delivery with high control and in a minimally invasive manner, which could potentially be applied in future pharmaceutical applications.

Candidiasis is a highly prevalent fungal infection caused by different species of the *Candida*fungus. The existence of multiresistant *Candida*strains is a public health problem [1]. Extracts from different parts of pomegranate containing ellagic acid and punicalagin have shown antifungal properties [2]. A crude dry extract of pomegranate peel (PPE) containing the bioactive compounds of interest identified by the HPLC method was used in the preparation of polymeric films for topical administration, aiming to obtain na alternative therapy to treat candidiasis. Films based on mixtures between poly(vinyl alcohol) (PVA) (Mw = 13,000 to 23,000 Da; hydrolysis = 87 to 89%) at 25% w/w and poly(ethylene glycol) triblock copolymer (P407; Mw = 12,600 Da) at 20% w/w were prepared by using the solvent casting technique, with different proportions between PVA and P407 (70:20, 60:30 and 50:40 v/v). A hydroalcoholic solution was used as the vehicle, with glycerin as the plasticizer and the PPE was added at 2.5% w/w in the blends. Polymeric films containing PPE were amber-yellow in color, shiny, smooth and without domain formation. The films were easy to remove from the molds and skin, maintaining the integrity during removal. All films demonstrated antimicrobial efficacy on strains of *Candida albicans*, *C. glabrata*, *C. krusei*and *C. tropicali*. The drying times of the films were around 1 h and 15 min (molds) and less than 30 min (skin). Average weight values varied between 0.034 (± 0.011) and 0.095 g (± 0.019); thickness varied between 0.090 (± 0.030) and 0.212mm (± 0.037); and residual moisture from 9.34% (± 0.002) to 12.46% (± 0.022). Physicochemical characterization tests of the polymeric films with and without PPE are in progress.

Tissue engineering in association with biomedical science has become an exponent for the use of biocompatible nanostructures in the repair of damaged tissues. The concanavalin A (ConA) lectin is a protein isolated from Canavalia ensiformis with the ability to bind to glycoconjugates, such as those present on cell surfaces. The objective of this work was the development of scaffolds based on polyvinyl alcohol functionalized with sodium alginate and ConA as a favorable environment for cell growth and multiplication. Nanofibers were prepared by formulating PVA and alginate homogenized in deionized. The formulation is inserted into a syringe, electrospinning occurs using a voltage of 24kV. The nanofibers obtained were activated by the coupling agents, aiming at stability in the immobilization of the ConA lectin. Electrochemical and optical techniques were used to evaluate the nanofibers, demonstrating the immobilization of the lectin on the polymeric surface, thus providing cell adhesion factors. The scaffold presents itself as an innovative alternative of three-dimensional material for use in the growth and proliferation of cells, with promising application as supports for skin grafts.

Teeth can be severely damaged and in cases of short dental crown it is necessary a pin as support. Nowadays, non-metallic prefabricated polymer composites pins emerged within the dental market [1]. The low cost, improved strength and modulus are the main reasons for their selection [2,3]. The aim of this research was the replacement of inorganic fiber by polypropylene fiber, PP, viewing application as dental pin. The thermogravimetric analysis (TGA) of the samples was conducted in TA equipment model Q500, 30–700 °C, 10 °C/min, under nitrogen. The reference pin curve showed onset temperature (Tonset) around 275 °C. Three stages of mass loss were detected: the first one below 100 °C and decays at 328 °Cand 410 °C. The polymeric matrix represented around 29% and the residue about 70% (inorganic reinforcement). TGA curve of pin containing PP fiber presented the maximumdegradation temperature at 160 °C and 250 °C, representing about 15% mass loss. A thirdstage occurred around 358°C representing around 75% of mass loos. The residue (around10%) was considered as carbonaceous material due to incomplete burning. Infrared spectroscopy and X-ray fluorescence analyses of the reference pin indicated that polymericmatrix was based on epoxy resin reinforced with glass and zirconia fibers. The improved technology for glucose (GL) detection will produce an increase in the quality life of millions of diabetics and pre-diabetics around the world. Numerous studies have been undertaken in recent years for the development of in vivo, minimally invasive, biologically compatible real-time quantitative GL sensors. In this sense, the development of biosensors with high sensitivity and low detection limits provides a new direction for medical and personal care. Two-dimensional materials such as graphene and hexagonal boron nitride (h-BN) are being used as biosensors due to their excellent detection performance [1, 2]. Several optical techniques have been used for GL detection, such as: infrared absorption, laser polarimetry, fluorescence modification of dyes. Most of these techniques are not molecule specific and can produce similar results with structurally similar molecules. However, Raman spectroscopy technique is unique, demonstrating the specific vibrational properties of each molecule. According to this, the objective of this work is to verify the possibility of using bilayers (2L), few layers (FL), multilayers (ML) and h-BN bulk as a GL biosensor using the Raman spectroscopy technique. For this purpose, the 2L, FL, ML and h-BN bulk were deposited on SiO2 substrates and subsequently characterized by Raman spectroscopy. Then a drop of commercial GL was placed on the surface of h-BN samples. Subsequently, Raman measurements, in the presence of the GL molecule were carried out in the same regions of the 2L, FL, ML and h-BN bulk samples, with the aim of comparing the Raman spectra before and after the GL deposition. Results of this comparison show that 2L are more sensitive to the GL molecule than FL and bulk and could be used as GL biosensors.

Central Nervous System (CNS) cancer is the 18th most incident cancer in the world, according to the World Health Organization (WHO), and in 2020, in Brazil, it represented 2.5% of all new cancer deaths [1]. Brachytherapy is a type of radiotherapy that positions the radioactive source close to (or in contact with) the tumor. Thus, the targeted region receives most of the dose, protecting the healthy tissues adjacent to the tumor. A promising radioactive source for use in brachytherapy for the treatment of CNS cancer is phosphorus-32 in a polymeric substrate. This source has been prominent as a minimally invasive treatment for craniopharyngiomas and in the treatment of metastatic bone diseases in general [2]. To produce such a source, it is necessary to search for possible molds that can conform the polymeric material into the desired format. Several tests were carried out to determine the best mold for the radioactive source manufacture. Different materials were tested to observe if the mold material would react with the source's components, silicone rubber mixed with orthophosphoric acid. In order to be considered a possible mold, the mixture should cure; if the cure did not concretize, the mold would be descarted. It was concluded that polystyrene (PS) obtained the best result, due to the ease of unmold after the resin curing process.

e-mail: carollramos10@gmail.com

Wollastonite is a material of great importance in the synthesis of biocompatible prostheses [1] and other medical and dental applications due to its ability to induce the formation of new bone tissue. Variations in the methods and nature of the precursors used in its synthesis can result in materials with different parameters, such as pore and mechanical properties, as well as the rate and products of their degradation, which can influence the biological response of the material [1]. In this study, we investigated different silica sources, such as TEOS (tetraethylorthosilicate) and silicic acid, to assess possible changes in the synthesis of α-wollastonite. The samples were prepared using a sol-gel method, making gradual adjustments to optimize the use of energy and reagents while achieving the desired quality of the final product. Physical and chemical characterization of the powders was carried out using X-ray diffraction (XRD), Fourier-transform infrared spectroscopy (FT-IR), Raman spectroscopy, and scanning electron microscopy (SEM). The results indicated that structurally similar and microporous materials were produced, with silicic acid being the most cost-effective precursor.

PREPARATION AND CHARACTERIZATION OF NEW SOLID DISPERSSIONS OF ISONIAZID TO INCREASEITS HYDROSOLUBILITY

Anderson Pedrosa da Silva[1], Paulo Roberto da Silva Ribeiro[1]

[1]Universidade Federal do Maranhão

e-mail: anderson.ps@discente.ufma.br

Isoniazid (ISO) drug used in the treatment of tuberculosis, belonging to Class III of the biopharmaceutical classification system (BCS), with good water solubility and low membrane permeability, contributing to the reduction of its bioavailability and therapeutic efficacy. Obtaining solid drug dispersions (SDDs) has been a strategy to improve the physicochemical properties of drugs, such as water solubility [1-3]. This study aimed to obtain and characterize new ISO SDDs from the interaction with malic acid (AML), using slow solvent evaporation (SSE) methanol. After obtaining the samples, they were characterized by powder X-ray diffraction (PXRD); and by simultaneous thermogravimetry, derivative thermogravimetry, differential thermal analysis (TG/DTG-DTA). The physical stability of these SDDs was performed by PXRD, as a function of time. The results obtained by PXRD of ISO-AML binary mixtures in molar ratios of 1:2 and 1:3 confirmed the amorphous nature of these new materials, as well as the occurrence of intermolecular interactions between ISO and AML, resulting in the formation of SDDs from co-amorphous type. The physical stability of these co-amorphous was investigated, and the co-amorphous of ISO-AML (1:2) showed stability for up to 49 days. While the co-amorphous of ISO-AML (1:3) was stable for up to 105 days. The TG/DTG results of the co-amorphous showed that these materials showed good thermal stability up to 135°C. The DTA curve of these solid dispersions did not show the occurrence of thermal events related to melting, confirming the amorphous nature of these materials. Assuming that amorphous materials are more water soluble than crystalline materials, the co-amorphous of ISO-AML (1:2) and (1:3) will contribute to increase ISO dissolution rates and its bioavailability. Thus, these materials are very attractive for the production of more effective drugs for the treatment of tuberculosis, as well as for reducing the side effects of this drug.

Printability of Carboxymethylcellulose and Laponite Hydrogels Using by Extrusion-Based Printer

Bruna Letícia de Camargo[1], INGRI JULIETH MANCILLA CORZO[2], Marcos Akira dÁvila[2]

[1]Universidade Estadual de Campinas (*Faculdade de Engenharia Mecânica*) , [2]Universidade Estadual de Campinas (*Materials and Manufacturing Processes*)

e-mail: camargo.bruna@outlook.com

Hydrogels based on Carboxymethylcellulose (CMC) and Laponite have shown promise as printable inks for tissue engineering applications and drug delivery [1,2,3]. In this study, we investigated the printability of CMC and Laponite hydrogels using an extrusion-based printer. We evaluated the effect of various printing parameters, such as printing speed, multiplier extrusion factor, nozzle diameter, and material concentration, on the printability and rheological properties of the printed structures. We used three different printing speeds (5,7 and 10 mm.s-1), three multiplier extrusion factors (100,125 and 150), and two CMC/Laponite concentrations (1CMC/2LAP and 1CMC/3LAP).

The 1CMC/3Laponite ink exhibited a pronounced pseudoplastic behavior with filament formation during printing and good printability using an Extrusion Factor of 100 and a Printing speed of 5 mm. s-1. On the contrary, the 1CMC/2Laponite ink did not exhibit good printability in most printing parameters studied.

Therefore, we demonstrated that studying printing parameters, printability, and rheological properties could provide insights regarding determining a suitable ink for use in the three-dimensional printing processes of hydrogels.

e-mail: sias.leticia@gmail.com

Polymeric nanoparticles (NP) are promising drug carriers for various diseases. Covalent bonds between polymers and fluorescent dyes can be used to prepare photoactive materials to detect and identify transporters in biological media. Proving that the covalent bond between the polymer and the dye is important to ensure that the observed fluorescence signal identifies the location of the NPs and therefore the target organic structure. However, some techniques are not always sensitive enough to detect these bonds [1]. The photophysical properties of Rhodamine B (RodB) in solution are affected by the chemical environment. In a protic medium, RodB is in the zwitterionic red form, whereas in aprotic solvents the solution is colorless, related to a lactonic specie [2]. The objective of this investigation was to explore this particular behavior of RodB to characterize the formation of the covalent bond between the polymer poly(ε-caprolactone) (PCL) and RodB. This study showed that the isomeric equilibrium associated with the molecular RodB did not occur, as the esterification of the RodB carboxylic acid prevented the formation of the lactonic form. Despite the very few amounts of RodB used to prepare the doped polymer, the proposed methodology showed to be solid to prove the covalent bond between polymer and fluorophore.

Nonsteroidal anti-inflammatory drugs, such as ketoprofen (KET), are commonly prescribed for pain and inflammation treatment (WONGRAKPANICH et al., 2018). However, the possibility of processing membranes with controlled drug release is a challenge in drug delivery (MORIE et al., 2016). Poly-L-lactic acid (PLLA) is a bioabsorbablepolymer commonly used in bone applications in form of membranes (ZAN et al., 2022). Theobjective of this study is to produce PLLA membranes incorporated with 15% (w/w) KETthrough the rotary jet spinning (RJS) process, and to characterize their properties and suitability for tissue engineering (TE) in bone regeneration. The membranes were fabricatedinto fibers and were tested to evaluate the processing and surface morphology, to determinethe chemical functional groups, thermal properties, wettability, absorption and, drug release in a simulated corporeal environment. The morphological results demonstrated thatthe RJS process successfully produced micrometric scale fibers. Chemical analysis revealedthe presence of characteristic functional groups of both PLLA and KET, without any toxic solvent residues. Thermogravimetric analysis revealed that the membranes exhibited thermal stability at human body temperature. The wettability test demonstrated that PLLAmembranes incorporated with 15% KET are hydrophobic. The mass loss test indicated thatan increase in the amount of KET incorporated into PLLA resulted in an accelerated processof mass loss. Additionally, the drug release test confirmed that PLLA membranes with 15%KET were capable of releasing the drug. In conclusion, the produced membrane shows promising potential for applications in bone tissue repair, owing to its anti-inflammatory properties.

Bone tissue engineering aims to treat injuries using 3D matrices (scaffolds), which repair the damaged tissue. As bone is the second most transplanted tissue after blood [1], the study of additive manufacturing for bone application is important due to the production of bioactive scaffolds customized to the specificity of each patient''s injury. Thus, this research produced scaffolds for use in bone tissue engineering using material extrusion-based additive manufacturing technology (Allevi 2, USA). The matrices are composed of poly(lactic-co-glycolic) acid (PLGA), which is a bioabsorbable polymer [2], and hydroxyapatite (HA) nanoparticles, which have osteoconductive properties [3]. The structures had different pore s (450 µm and 900 µm) and 10% w/w HA added (PLGA-HA). Scanning electron microscopy (SEM) results showed that the pore s of the PLGA-HA scaffolds were equivalent to the proposed. Fourier-transform infrared spectroscopy (FT-IR) revealed the characteristic peaks of PLGA and HA, and no peaks corresponding to the solvent used. Thermogravimetric analysis showed that the concentration of HA was added accordingly. Finally, the scaffolds presented osteoconductive properties in vitro. Thus, the scaffolds proposed in this study were successfully processed and have a great potential to promote osseointegration for bone applications.

Ti alloys have been studied for biomedical application due to their corrosion resistance, biocompatibility, and better association between their mechanical properties [1-3]. The objective of this work was to analyze the properties and microstructure of treated Ti-12Mo-25Nb alloy. Ti alloys have been studied for biomedical application due to their corrosion resistance, biocompatibility, and better association between their mechanical properties [1-3]. The objective of this work was to analyze the properties and microstructure of treated Ti-12Mo-25Nb alloy. This alloy was produced by arc melting with non-consumable tungsten electrode in controlled atmosphere of argon. The alloy was treated at 950 °C by 1hand water quenching. The material was characterized by X-ray diffraction and optical microscopy. The mechanical characterization was realized by Vickers hardness and Young' smodulus by was obtained by the ultrasound technique. The results of the microstructural characterization showed only the presence of the β-Ti phase. Vickers hardness equal to 210HV and Young' s modulus 74 GPa. With the results obtained, it can be observed that theTi-12Mo-25Nb alloy presents potential for biomedical application.

Acknowledgments
This work was supported by CNPq, CAPES and FAPERJ.

An aqua-(glutaminato)-(1,10-phenanthroline)-copper nitrate monohydrate complex was synthesized and its vibrational properties were evaluated by Fourier-transform infrared (FT-IR) and Raman spectroscopy. In addition, quantum chemistry calculations were performed to obtain an understanding of the relationship between the structure and reactivity of metallic complexes. The optimization of the geometry of the titled complex and the vibrational frequencies were performed using the functional PBE1PBE together with the set of basis functions 6-311++G(d,p) for C, O, H, and N atoms, and the Stuttgart-Dresden basis set for copper (Cu) atom, which includes effective core potentials for the relativistic treatment of core electrons and double zeta polarized basis for valence electrons. Chemical, electronic and vibrational properties were properly investigated through experimental and theoretical approaches, including a solvation effects study based on the polarizable continuum model, using methanol and water as solvents. Thereby, the results of this study indicate the potential and relevance of using the density functional theory in the chemistry of organic and metallic compounds, opening a way for advances in understanding the reactivity, structure, and vibrational proprieties of coordination complexes. Finally, the vibrational calculations showed good accordance with experimental Raman and IR results.

Role of aspartic acid in the synthesis of spherical vaterite: study of the crystallization mechanisms in aqueous medium using cryo-transmission electron microscopy techniques

Noemi Raquel Checca Huaman[1], Alexandre Malta Rossi[1], André Rossi[1] [1]Centro

Brasileiro de Pesquisas Físicas (*COMAN*)

e-mail: noemiraquelchecca@gmail.com

Vaterite, is the least stable phase of calcium carbonate ($CaCO_3$). The phase vaterite mainly exists in biological systems, rather than in nature [1]. However, some amino acids could stabilize the vaterite phase. Vaterite is expected to have potential applications for biomedical areas as preservative containers for growth factors and encapsulating carriers for drugs because of its high solubility, high specific surface area and high dispersion. Aspartic acid is amino acids that could control the nucleation and the growth of crystallization on increasing the rate of nucleation and delaying the growth of crystal. However, the role of amino acids on the crystallization behavior is still difficult to understand, and the mineralization mechanism of vaterite does not have a complete, reasonable explanation. In this work, we present a sequential analysis of the different steps of $CaCO_3$ synthesis with aspartic acid in aqueous medium. The systematic study of growth mechanisms in the maturation phase of the synthesis was performed using the technique of Cryo -Transmission Electron Microscopy (Cryo-TEM) using the modes of HRTEM, SAED, EDS and EELS. This technique allows preservation of 3 µL of the specimen by vitrification at different stages of the synthesis process, preventing their modification during drying. For the synthesis of $CaCO_3$ we use $CaCl_2.2H_2O$, Na_2CO_3 and aspartic acid (0.1M) what were obtained from Sigma Aldrich. Aqueous solutions of the reactants was made using milli-Q water. We also analyzed the dry sample of the synthesis with other techniques that that need large amounts of material, such as XRD, SEM, FTIR and TGA. The experimental results indicate that the addition of aspartic acid inhibited the growth of calcite, presenting by XRDa 90% of the vaterite phase and SEM clearly shows nanostructures with diameters of micrometers formed by nanoparticles with diameters of 30 nm.

e-mail: deidyane.ferreira@hotmail.com

Organic-inorganic hybrids using poly(2-hydroxyethyl methacrylate) p(HEMA) as bioactive coatings for Ti-6Al-4V alloy have been the subject of much research [1]. However, the study of corrosion resistance and biocompatibility simultaneously of this material is limited. Therefore, the present work aimed to evaluate the structural and surface behavior, corrosion resistance and bioactivity of the Siloxane-p(HEMA) hybrid coating deposited on Ti-6Al-4V alloy. The preparation of the hybrid prepared by the sol-gel method occurred in three stages. The first consisted of the copolymerization of 2-hydroxyethyl methacrylate, with 3-(trimethoxysilyl)propyl methacrylate (organic phase), using benzoyl peroxide as thermal initiator and tetrahydrofuran as solvente. In the second step, the inorganic phase was obtained by mixing tetraethyl orthosilicate, etanol and water acidified with HNO3 (pH 1). The third stage consisted of mixing the inorganic phase with the organic one to obtain the hybrid. The samples were analyzed by Fourier Transform Infrared Spectroscopy, Scanning Eléctron Microscopy, Energy Dispersive Spectroscopy, Electrochemical Impedance Spectroscopy, potentiodynamic polarization curves and bioactivity assay. The results confirmed the formation of the hybrid and the achievement of a uniform and homogeneous surface coating on the alloy Furthermore, the corrosion resistance and bioactivity have been significantly improved. These results indicated that the Siloxane-p(HEMA) hybrid coating applied on Ti-6Al-4V alloy can act as a promising alternative for biomedical applications.

Porous bioceramics, which are known as scaffolds, can be used for bone tissue replacement or repair. In particular, alumina/zirconia (Al_2O_3/ZrO_2) bioceramics have excellent mechanical properties and chemical stability when compared to other materials. Due to their bioinertness, these biomaterials can be combined with calcium phosphates (Ca-P) to improve their bioactivity. Furthermore, the stimulation of bone formation through osteogenesis may be enhanced by incorporating strontium ions (Sr^{2+}) into the Ca-P structure. Herein, we studied the fabrication and characterization of Al_2O_3/ZrO_2 scaffolds (5 vol% in nano-sized ZrO_2 inclusions) using the gelcasting method and biomimetic coating with enriched with Sr^{2+}. Following scaffold fabrication, chemical surface treatment with phosphoric acid and coating with Synthetic Body Fluid (SBF) 5x more concentrated enriched with Sr^{2+} ions were performed for 14 days. We then characterized the scaffolds in terms of their morphology, porosity, and phosphate layer formed after incubation in SBF. In general, we observed the porous morphology of the scaffolds with high interconnectivity between the mostly spherical pores. Microtomographic analysis (µCT) revealed that approximately 60% of the pores present in the scaffolds had diameters between 120 and 350 µm, suggesting that the obtained scaffolds may promote bone tissue growth. Biologically interesting Sr-containing phosphates and Ca-P phases were observed on the surface of the scaffolds, suggesting that these materials are suitable for bone tissue engineering and bone repair and regeneration therapies.

Bioactive borate glasses exhibit fast and complete conversion to hydroxyapatite (HA) when compared to bioactive silicate glasses [1-2]. Cerium-doped bioactive glasses can improve the performance of HA formation and fast bioactive response [3]. The aim of this study is to evaluate the influence of cerium oxide on the chemical durability of borate glasses in the vitreous system ($64B_2O_3$-$2P_2O_5$-(18-x)CaO-$16Na_2O$, with x = 0.5, 1, 1.5, and 2 mol% of CeO_2). The samples were synthesized by melt-quenching method and were analyzed by XRD and FTIR, before and after immersion in Simulated Body Fluid (SBF) for 28 days. The pH measurements were performed during the immersion period. Cytotoxicity was assessed on RAW-247 macrophages. The XRD diffractograms confirmed the amorphous nature of the samples and the FTIR spectra showed absorption bands characteristic of borate glasses. After imersion in SBF, the XRD diffractograms showed the presence of characteristic peaks of HA and $CePO_4$, with attention to the sample with 2 mol% CeO_2. The FTIR spectra of immersed samples showed the presence of phosphate groups (HA e $CePO_4$). The pH data indicate higher ion exchange between Ce-doped samples and SBF. The samples did not showed toxic behavior. The results showed that CeO_2 doped glasses improve the HA formation and demonstrate high bioactive behavior. Finally, the samples exhibited potential for tissue and bone regeneration.

Study of the thermal decomposition of telluric acid and coacervate with telluric acid

Thaís Lourenço Oliveira[1], Patrick de Souza Carvalho[2], Maurício Antonio Pereira da Silva[2], Luiz Fernando Cappa de Oliveira[2]

[1]Universidade Federal de Juiz de Fora (*Química*) , [2]Universidade Federal de Juiz de Fora

e-mail: thaislourenco@ice.ufjf.br

Telluric acid, molecular form $Te(OH)_6$, is a white monoclinic crystal that is very soluble in water, consisting of octahedral molecules stable in aqueous solution because it is a weak acid [1]. Its thermal decomposition was studied by Differential Thermal Analysis (DTA) and Thermogravimetric Analysis (TG). The four phase transitions, all endothermic. According to the literature [2] the mass losses refer to the phase transitions that lead to the compounds $(H_2TeO_4)_n$, $H_2Te_2O_7$, $TeO_3$and TeO_2, respectively. A gradual change in the profile of the Raman spectra is observed, indicating the occurrence of the phase transitions described above. The large broadening of the bands reflects the low crystallinity of the compounds formed, making it difficult to assign bands. However, the telluric acid sample heat-treated at 500 °C exhibits a Raman spectrum similar to that of tellurium oxide (IV). From this material, $Te(OH)_6$, its calcium polyphosphate coacervate was obtained, which were analyzed by Raman spectroscopy and showed that telluric acid was incorporated into the phosphate network of the coacervate. From the coacervate with telluric acid, its thermal treatments were carried out, which were later analyzed by Raman spectroscopy.

The high reactivity of blood with any non-endothelial/natural surface is a major challenge in the development of long-term circulatory assistance devices. Dedicated to blood contact surfaces were developed by manipulating the surface energy of pure titanium using nanosecond laser texturing followed by Diamond-Like-Carbon coating [1]. The difference in coating thickness on the textured surface generated two conditions: (a) super-plasmophobic surface, capable of preventing contact interaction with blood, and (b) super-plasmaphilic, promoting the anchorage of blood constituents susceptible to endothelialization. A 20-week in vivo experimental study demonstrated preliminary results and trends of how this behavior will be in the practice of mechanical circulatory support. Four groups with three animals were considered for each type of implants, one Reference Material and three different Test Samples. The implant was positioned in the abdominal aorta of 300 g Wistar rats and the effects of the hemodynamic interaction were evaluated without anticoagulant. After twelve weeks, the implants were extracted and subjected to qualitative analysis by low-vacuum scanning electron microscopy and chemical analysis by X-ray Energy Dispersion. Surface regions that remained in intense blood flow showed more significant interaction responses and those that remained in contact with the aortic wall, encapsulation by the endothelial tissue. The ultra-fast laser texturing process will need to be improved to ensure shear strength and applicability in parts with unconventional geometry. The coating with a greater thickness of diamond-like carbon showed an inhibitory effect on the endothelialization process, even under a super-plasmaphilic effect. Swelling and degradation properties of chitosan scaffolds containing grape seed oil for skin tissueregeneration

Lívia de Pádua Ferné[1], Larissa Ribeiro Lourenço[1], Juliana Marchi[1]

[1]Universidade Federal do ABC (*Centro de Ciências Naturais e Humanas*)

e-mail: livia.ferne@aluno.ufabc.edu.br

Regenerative medicine is a prominent area aiming the development of biomaterials for application in the repairment of injured tissues. The skin tissue performs important functions for the maintenance of the body and its injury can lead to complications in the patient's health. Chitosan is a promising biomaterial for tissue regeneration due to suitable characteristics such as biocompatibility and biodegradability, cost-effective production, and processing versatility. Also, it is possible to incorporate other substances, aiming specific biological properties for the treatment of different biological tissues. Grape seed oil can be an interesting alternative, which can optimize the tissue regeneration process due to its antioxidant, anti-inflammatory and antimicrobial characteristics. Swelling and degradation are very important characteristics because they affect tissue-biomaterial interface and subsequent cell adherence and attachment. In this work, chitosan scaffolds containing grape seed oil in different proportions were obtained by 3D printing. The properties of swelling and degradation of the developed materials were evaluated up to 21 days. Theresults indicate that the presence of the grape seed oil reduced water absorption anddegradation rate of the chitosan scaffolds. Thus, the incorporation of such oil can modulatethe degradation of chitosan based materials, aiming wound dressing applications.

The complexes prepared from 1,10-phenanthroline have demonstrated antitumor potential since this ligand could bind with DNA [1]. Silver, in turn, has known its biological activity for thousands of years [2]. In this study, a complex of silver(I) and 1,10-phenanthroline was synthesized, reported in the literature as bis(1,10-Phenanthroline-N,N’)-silver(i) nitrate [3]. The material was synthesized using the slow solvent evaporation technique. X-ray diffraction technique (XRD) and Rietveld refinement, demonstrate that the material crystallizes an orthorhombic structure with the Fddd-space group. Thermal properties were studied using thermogravimetry (TG), differential thermal analysis (DTA), and differential scanning calorimetry (DSC) techniques. The material has shown thermal stability up to 373 K. The vibrational modes of the complex were measured using the Fourier Transform Infrared Spectroscopy (FTIR) technique. The results demonstrate that the material is promising for applications such as antitumor.

Acknowledgments:
We thank the FAPEMA, CAPES, CNPQ for their support in this research.

e-mail: kamila_rodriguesabreu@hotmail.com

Metal complexes can easily interact with proteins and nucleic acids through the complexation of metal ions with the ligand through electrostatic reactions and the formation of hydrogen bonds [1]. Thus, they have been used for a long time to treat diseases caused by different types of microorganisms, making it interesting to carry out studies to synthesize this type of material. They are heavily investigated due to their dual antimicrobial and antitumor activity. Thus, this work aimed to synthesize the complex bis((μ_2-hydroxo)-2,2' -bipyridyl)-nitrate-copper(II)) [2] by the slow solvent evaporation method and perform the characterization of the structure by X-ray diffraction (XRD), vibration by Fourier transform infrared spectroscopy (FT-IR) and thermal by thermogravimetric analysis (TG), differential thermal analysis (DTA) and differential scanning calorimetry (DSC). XRD at room temperature showed that the material crystallizes in a triclinic system with space group P1(2). The FT-IR spectrum confirms the complexation of Cu(II) with bipyridine, showing bands at 1372 and 1637 cm^{-1} attributed to the stretching modes of the bipyridine nitrogenatoms with the copper atoms. The thermal analysis of TG -DTA and DSC showed that thecrystal has thermal stability up to 200°C.

Synthesis and characterization of multifunctional mesoporous silica nanoparticles containing gold nanoparticles and gadolinium as theranostic system

André Felipe de Oliveira[1], Isabela Barreto da Costa Januário Meireles[1], Edesia Martins Barros de Sousa[2]

[1]Centro de Desenvolvimento da Tecnologia Nuclear (*SENAN*) , [2]Centro de Desenvolvimento da Tecnologia Nuclear (***Serviço de Nanotecnologia***)

e-mail: andrefelipe.oliveira88@gmail.com

Mesoporous silica nanoparticles are well-known materials used as drug delivery systems due to their biocompatibility, well-defined pore diameter, and high surface area [1]. As well as gold nanoparticles are primarily studied as nanoplatforms for theranostics cancer due to their optical properties which can be used for diagnosis and treatment [2]. Moreover, gadolinium remains the most common MRI contrast agent to enhance the brightness of the region of interest [3]. This study used gold nanoparticles and gadolinium oxide incorporated into the silica matrix to design a theranostic system. The techniques used to characterize the nanocomposites were infrared spectroscopy (FTIR), ultraviolet-visible spectroscopy (UV-Vis), thermogravimetric analysis (TGA), nitrogen adsorption, scanning electron microscopy (SEM), dynamic light scattering (DLS), X-ray fluorescence (XRF), X-ray diffraction (XRD), and vibrating sample magnetometry (VSM). To confirm the presence of gadolinium and gold in the silica network, UV-Vis, nitrogen adsorption, XRF, XRD, SEM, and VSM techniques were used. The results showed that nanocomposites were successfully obtained and the incorporation of gold nanoparticles and gadolinium in the MCM-41 matrix was achieved, indicating the system has a potential application in cancer treatment and diagnosis.

Synthesis and characterization of the SiO_2-Na_2O-CaO-P_2O_5 glass-ceramic doped with MgO by the sol-gel method

Magno de L. Silva[1], Thaís M. T. Nascimento[1], Francisca M. M. Pereira[2], Raquel A. P. Oliveira[1]

[1]Fundação Universidade Federal do Vale do São Francisco (*Instituto de Pesquisa em Ciência dos Materiais*), [2]Universidade Federal do Cariri (*Centro de Ciências e Tecnologia*)

e-mail: magnolima9@gmail.com

Bioactive glass-ceramics used in bone regeneration due to their bioactivity, biocompatibility and ability to form a hydroxyapatite layer [1]. Furthermore, syntheses containing MgO as a dopant demonstrated better adhesions, cell proliferation and cell differentiation [2]. The aim of this work is to synthe and characterize SiO_2-Na_2O-CaO-P_2O_5 glass-ceramic (SNCP) doped in different concentrations of MgO (0.5, 1 and 1.5 %mol). Samples of composition $50SiO_2$-$25Na_2O$-21CaO-$4P_2O_5$ (% mol) were prepared by the sol-gel method [3], with the reagents: $Na_2SiO_3.5H_2O$, P_2O_5 and $Ca(NO_3)_2.4H_2O$. The gel obtained was aged for 5 days at room temperature in a desiccator and dried in an oven at 60 °C/72 h. The powder was homogenized in a mortar with the aid of a pestle, both of agate, and were transferred to a Pt:5%Au crucible for heat treatment in a resistive furnace under the conditions: 200 °C/40h, 600 °C/5 h, 800 °C/3 h and 1000 °C/2 h. The heating rate was 10 °C/min, with slow cooling to room temperature. X-ray diffraction (XRD), scanning electron microscopy (SEM)and Fourier transform infrared spectroscopy (FTIR) were performed. XRD analysis showedthe formation of $Na_4Ca_4Si_6O_{18}$, $Na_6Ca_3Si_6O_{18}$ and Ca_2SiO_4 phases in the structure of pure and MgO-doped glass-ceramics. SEM analysis showed that the samples have particles of irregular shapes and varying sizes. The FTIR data showed bands at: 1082 and 1035 cm^{-1} ofSi-O-Si asymmetric axial strain and at 621 and 574 cm^{-1} of P-O angular strain. Preliminary results show the viability of the synthesis the SNCP glass-ceramic by sol-gel method withdifferent concentrations of MgO and a great potential for bone regeneration.

The study of coordination complexes of transition metals has been increasingly performed due to their promising biological activities. Cobalt stands out among metals due to its presence in vitamin B12 and its important role in the biochemical reactions of metalloenzymes [1]. Additionally, 1,10-phenanthroline is a formidable planar bidentate ligand that easily coordinates to transition metals, forming coordination complexes in a crystal lattice [2]. The aim of this work was to synthesize a coordination complex containing the cobalt(II) transition metal ion coordinated to the 1,10-phenanthroline and malic acid ligands (CoPhenMale), characterize, and study its thermal, vibrational, and biological properties, by means of the techniques of X-ray diffraction (XRD), differential thermal and thermogravimetric analysis (DTA/TG), Fourier-transform infrared spectroscopy (FT-IR), Raman spectroscopy, and anticancer activity tests. XRD results showed that the synthesizedcomplex crystalizes in the triclinic crystal system of the P1 space group. Rietveld refinementproved the crystalline structure since the parameters obtained are in a good agreement withdata available in the literature [3]. The DTA/TG results showed that the crystal presents agood thermal stability, with endothermic dehydration events. The analyses of the spectra provided a detailed attribution of the main bands related to the vibrational modes of thecomplex. Partial results of antitumor activity tests demonstrate a reduction of 60% of cellviability in breast cancer cell lines MDA-MB-231 and MCF-7 after 48 h of treatment. Fromthis study, we determined several properties of the material obtained and confirmed that itpresents promising possible applications as an antitumor agent.

e-mail: prof.nessaquimica@gmail.com

The present work shows the route of synthesis and the characterization of the complexes $[Ru(Cl)_3(H_2O)_2(3\text{-}pina)].5H_2O$ C1, $[Ru(Cl)_2(H_2O)_3(3\text{-}pina)]Cl.1/2H_2O$ C2 and $[RuCl(NH_3)(H_2O)_2(3\text{-}pina)](BF_4).1/2H_2O$ C3, with the linker N-(3-pyridyl)-isonicotinamide (3-pine), and its application in tests of microbicidal and phagocytic activities for Staphylococcus aureus (Gram positive) and Escherichia coli (Gram negative) bacteria. Characterizations by TG-DTG and TG-DSC show loss of C1 mass in three steps, related to the oxidative degradation process of (3-pin) with the formation of RuO_2 residue and error 0.337% (Exp.= 64.431%; Calc = 64.094%). C2 suffers mass loss in five stages with the formation of RuO_2 residue and error of 0.584% (Exp. = 71.080%; Calc. = 71.660%). C3, undergoes mass loss in six steps with an error of 0.926% (TG/exp= 74.451%; Calc= 73.525%) and RuO_2 residue [1]. Biological applications were carried out in C2 and C3, as for compound C1 it is insoluble in water. The viability analysis was performed for compounds C2 and C3 and free ligand and showed no toxicity against the PBMC cell. Microbicidal and phagocytic activity tests for bacteria (Gram positive) and (Gram negative)[2] indicate the antimicrobial and phagocytic potential of the compounds. Agreement: Federal University of Mato Grosso (UFMT); Materials Research Lab (MRL);Chronoimmunomodulation Laboratory and CAPES Palavras-chave: Rutênio, ligante 3-pina, atividade biológica. References. Synthesis, characterization, and vibrational study of binuclear maleatocopper(II) complex with phenanthroline

Jad Lorena Feitosa Simplício[1], Jailton Romão Viana[1], João Gomes de Oliveira Neto[2], Adenilson Oliveira dos Santos[1]

[1]Universidade Federal do Maranhão, [2]Universidade Federal do Maranhão (*PPGCM*)

e-mail: jady.JLFS@gmail.com

Crystalline complexes containing transition metals and bidentate chelating compounds play primary roles in numerous biochemical processes [1]. Besides enhancing the biological activity of different ligands, copper complexes provide the development of antacid, anti-inflammatory, antiviral, antitumor, antimalarial, alzheimer''s treatment properties due to their neuroprotective action [2]. Thus, this work aimed to synthe and characterize binuclear copper(II) complexes with the ligands 1,10-phenanthroline and maleic acid to study their structural, vibrational, and thermal properties. The crystal was synthed with an equimolar ratio of the compounds by the slow solvent evaporation technique at room temperature. The crystalline complex containing two Cu2+ ions, two molecules of 1,10-phenanthroline, two maleates, and four water molecules (Cu2Fen2Male2) was characterized by X ray diffraction (XRD), differential thermal analysis, and thermogravimetric analysis (DTA/TG), Fourie transform infrared spectroscopy (FTIR) and Raman. The XRD results and Rietveld refinement confirms that the complex crystallizes in a monoclinic structure (space group C2/c), with four molecules per unit cell (Z=4). The lattice parameters showed good agreement with the literature [3]. The vibrational absorption and scattering modes exhibit the primary bands associated with the deformations and stretching of the Cu2+ ions with oxygen and nitrogen atoms to which they are bonded. The thermal analyses show that the complex has thermal stability up to 320K.

Acknowledgments: We thank the FAPEMA, CAPES, CNPQ for supporting this research.

SYNTHESIS OF BARIUM HEXAFERRITE DOPED HYDROXYAPATITE SCAFFOLDS PREPARED BY THE FREEZE-CASTING METHOD

Kerolaine de Jesus Tavares[1], Alysson Martins Almeida Silva[1]

[1]Universidade de Brasília (*Department of Mechanical Engineering*) *e-mail: tavareskerolaine@gmail.com*

Fractures and bone defects continue to be a problem that significantly affects the economy of the world and the patient's quality of life. The search for synthetic materials that are biocompatible, osteoconductive and osteoinductive has been a very promising alternative for the treatment of fractures and bone diseases [1]. Hydroxyapatite has characteristics similar to that of bone and its use has been disseminated in several studies, since the development of hydroxyapatite scaffolds for bone regeneration has been carried out. there.The objective of this article is to study the influence, effect and viability of thehydroxyapatite monolith through the freeze-casting technique and dop it with barium hexaferrite that will be produced by the sol-gel combustion method. The structure of hydroxyapatite doped with barium hexaferrite was investigated by thermogravimetric analysis (TGA), X-ray diffraction (XRD), compressive strength assay, infrared spectroscopy,gas adsorption method, scanning electron microscopy (SEM), microtomography, and Archimedes principle. By increasing the calcination temperature of barium hexaferrite, theoxidation process occurs, but when doping occurs, this phenomenon is not observed. Theporosity increased as the amount of barium hexaferrite increased, resulting in a more porous region at the top of the monolith and denser in the region that is in contact with thecopper dowel.

Synthesis of gadolinium-doped hydroxyapatite nanoparticles using a microwave-assisted hydrothermal method

JESSICA PAULINE NUNES MARINHO[1], Edésia M. B. Sousa[2]

[1]Centro de Desenvolvimento da Tecnologia Nuclear (*SENAN*) , [2]Centro de Desenvolvimento da Tecnologia Nuclear (*Serviço de Nanotecnologia*)

e-mail: jessicapauline.marinho@gmail.com

Bioceramics such as hydroxyapatite (HA) have been widely researched for biological applications due to their properties related to their chemical similarity with the inorganic phase of bones and teeth [1]. Furthermore, the flexibility of its structure allows a series of ionic substitutions, which gives it new properties. Doping with lanthanide ions has been widely investigated due to the similarity of the ionic radius of calcium (Ca^{+2}). In particular, gadolinium ions (Gd^{3+}) have been used in clinical practice as a contrast agent, in the form of metalorganic complexes, for nuclear magnetic resonance (NMRI). However, the Gd^{3+}ion has high toxicity when free in the bloodstream and, in the long term, individuals exposed to gadolinium-based contrast agents may have health problems related to the accumulation of Gd^{3+}in tissues and organs [2]. In this sense, due to the high stability of the HA structure, the production of HA nanoparticles doped with Gd^{3+}(n-HAGd) can be an alternative to toxicity problems. Among the different existing methods for HA synthesis (hydrothermal, precipitation, sol-gel, pyrolysis, hydrolysis, sonochemical, solid-state synthesis), microwave-assisted hydrothermal synthesis has the advantage of shorter synthesis time and more efficient heating. Based on the above, the objective of this work is the synthesis and characterization of HA nanoparticles doped with different concentrations of Gd^{3+}(n-HAGd). n-HAGd nanoparticles were synthed using the microwave-assisted hydrothermal method. The synthed nanostructures were characterized by XRD, TEM, FTIR, TGA, and VSM techniques. The results indicated the obtainment of carbonated n-HAGd with paramagnetic properties with the potential to be used as a contrast agent in NMRI.

Phosphate-based bioglasses have been studied in recent years as a promising material for applications in dentistry and bone repair. These materials must have antibacterial characteristics and have the ability to induce bone formation. In this work, phosphate glasses with the structure $55P_2O_5-5ZnO-(30-x)Na_2O-10Al_2O_3-xTiO_2$(x=0;0.1;0.5;1 and 2mol%) were synthed using the melt tempering technique. The reagents, in powder form, were mixed, placed in a crucible and placed in an oven at a temperature of 1200°C. The molten material was poured into preheated molds at a temperature of 435°C and subsequently taken to the oven for annealing. Characterizations of MIR (Mid-Infrared), NIR (Near-Infrared), UV-Vis Spectroscopy were carried out in order to obtain the absorption coefficient and Band Gap energy information of the materials. Vickers microhardness measurements showed the difference in hardness between the synthed materials. Scanning Electron Microscopy (SEM) were carried out in order to observe the formation of apatite in the material. Finally, they were conducted to verify the cytotoxicity of the synthed glasses. The materials showed promise for application as bioglasses.

e-mail: jaysoncabral@hotmail.com

The present work seeks to explore the properties of metal complexes in order to increase the efficiency of DNA strand cleavage by means of the binding affinity of the metal complex with DNA. 1,10-phenanthroline (fen) is able to bind to DNA and L-isoleucine is essential for the development of skeletal muscle tissue [1]. Based on this possibility, this work aimed to synthesize by the slow solvent evaporation method and characterize the physical and chemical properties of copper(II) crystal, 1,10-phenanthroline and Isoleucine. The obtained crystalline materials were characterized by X-ray diffraction (XRD), thermogravimetric analysis (TG), differential thermal analysis (DTA), FT-IR spectroscopy, Raman and DFT study. The crystal was obtained and its structure confirmed by refinement using the Rietveld method. The data are in agreement with that reported in the literature [2]. The TGand DTA analyses showed that the material has thermal stability up to 323 K, higher thanthe human body temperature, undergoing phase transformation by dehydration due to theexit of free water from the compound. The FT-IR and Raman analysis evidenced the complexation of the copper(II) ion with the 1,10-phenanthroline and Isoleucine molecules, since the vibrations observed are associated with these molecules. The chemical reactivitydescriptors obtained by the DFT method indicate that the complex has the potential toparticipate in chemical reactions and interact with biomolecular targets. These results suggest that the complex has the potential to be used in chemotherapeutic treatment ofcancer cells.

The use of metallic materials in ophthalmology is constant, both in the surgical area and in the clinic, present in the treatment of ocular trauma, infectious diseases or in the simple correction of refractive errors, with this the search for improvements and improvement of the tools becomes increasingly necessary . In ophthalmology, a stainless steel trephine is used, martensitic stainless steel of the AISI-420 type is widely used in the manufacture of surgical tools, it is designed for performing corneal surgeries, it needs to have a good cutting edge, a thin and symmetrical blade causing a perfect flattening in conformity with the córnea. Because it has a high demand and high costs, it presents a problem for the health system, whether public or private. This work was motivated by the high cost of the tool and because it has a short useful life in the surgical procedure, it will evaluate the chemical composition, the hardness, the microstructure, the surface treatments and the wear resistance, and its objective is the improvement of stainless steel 420 via plasma nitrogen deposition under different conditions forming a new layer on the surface of the material, aiming at reducing the cost and improving the useful life of this cutting tool, withthis characterizations for evaluation will be carried out to qualify the best possible technique accordingly with results of greater hardness, less wear and improved product life,obtaining the best performance and carrying out its functions correctly.

Temperature dependence to exchange native ligands in post-synthesis reactions for zirconia nanocrystals

Walter Sperandio Sampaio[1], Cleocir Jose Dalmaschio[1], Pablo Santana Lemos[2]

[1]Universidade Federal do Espírito Santo (*Departamento de química*) , [2]Universidade Federaldo Espírito Santo

e-mail: walter.sampaio@edu.ufes.br

From a chemical synthesis route, the surface ligands that cover nanocrystals (NCs) are required to produce nanomaterials with controlled growth and stabilized surface. Changing the surface ligands in a second synthesis step has been used to modify the surface of nanomaterials and achieve desired behaviors without changing the characteristics of the produced NCs[1]. In this work, ZrO_2 NC was synthesized using benzyl alcohol as solvent and zirconium butoxide in butanol as a metallic precursor. NCs with size around 5 nm, narrow size distribution and cubic crystalline phase were obtained. Native capping ligands from the synthesis were identified as benzoates and butanoates from the solvents used in the synthesis [2]. Ligand exchange was performed by immersion in excess synthesis solvents at room temperatures and near the boiling point of the solvents. Characterization by FTIR spectroscopy indicated that temperature plays a fundamental role in removing native ligands from the synthesis, and it was also possible to identify different modes of binding benzoate and butanoate ligands with NCs surface. Thermogravimetric analyses allowed quantification of the ligands and confirmed different binding forces with the surface of the NCs. We conclude that for ligands precursors with closed pKa value, high temperatures are required to exchange almost all native ligands from NCs surface without changing the crystalline phase. Those results contribute to the study of the composition of the binders in the ZrO_2 NCs and reveal that the surface modification treatment used can be adjusted to control the covering capping agents in NCs.

Propolis is a resinous substance of complex composition, formed by gummy and balsamic material, collected by bees from different types of trees, this product has been the subject of pharmacological studies due to its antibacterial, antifungal, antiviral, anti-inflammatory, antioxidant, and antitumoral properties[1]. Microencapsulation prevents the loss of substances by oxidation or volatilization, as well as controlling the release of aromas, and loss of nutrients, and preserving the color and flavor of the encapsulated agent[2]. In this work, the study of thermal degradation in greenish-brown propolis microcapsules obtained using a Spray Dryer was carried out, the objective was to evaluate the stability of the microcapsules about the protection of the active compounds present in the extract, such as the content of flavonoids and phenols. The extract and the microcapsules containing greenish-brown propolis extract presented in their composition full flavonoid content of 5.15% and 1.13%, total phenols of 14.16 and 4.81% in terms of gallic acid, total phenols of 16.53% and 6.00% in terms of catechin, antioxidant activity with IC50 values of 13.77 μg/mL and 60.80 μg/mL, respectively, and thermal analysis showed the thermostability of the studied extracts. According to the TG analyses, the mass loss was 19.152% from 26.02 to 215.90 ºC, in the first moment, and afterwards, the mass loss was 52.486% from 215.90 to 531.53 ºC. These data mean, respectively, the loss of volatile compounds and the decomposition of the encapsulating material. It is worth mentioning that the formation of greenish-brown propolis microspheres has not yet been reported in the literature, demonstrating this work's originality. e-mail: ailda.luz@hotmail.com

The present study reports the preparation of borophosphate glasses (40-x/2)B_2O_3-(25-x/2)P_2O_5-7CaF_2-20Na_2O-8CaO-xBaO (x=0, 5, 7.5 and 10 % in mol) in order to investigate the role of BaO on its physical, radiopacity, and bioactive properties. The samples were synthesized by melting-quenching technique and submitted to bioactivity test in SBF for 28 days. Before SBF immersion, the samples were characterized by XRD, FTIR, radiography; ionizing radiation shielding parameter were also calculated. After SBF immersion, pH measurements, XRD and FTIR were also performed to investigate the bioactivity of the glasses. Cytotoxicity test were user to evaluate the influence of BaO in cell viability. Results before SBF immersion, XRD proves the amorphous nature of the samples, FTIR indicated structural changes in the glasses with the increase of BaO. It was possible to compare the radiopacity of the 0 mol% BaO sample with aluminum and dentin of the same thickness (1mmEq/Al). The other samples have the value of 1.68; 2.29 and 2.90 mmEq/Al (5, 7.5 and 10 mol% with BaO, respectively)[1]. The mass attenuation coefficient (MAC) shows that the attenuation of the radiation in the low energy region of X-rays (60KeV) is notably increased with the BaO content and reaches a value of up to 16 times that of common concrete for the sample with 10% BaO, Results after SBF immersion, final measured pH value between the samples decreased with the increase in the concentration of the BaO, indicating a decrease in the ionic release rate with the increase in this concentration. The XRD and FTIR analyses, shows the presence of hydroxyapatite and fluorapatite phases. The cytotoxicity results indicate that all prepared samples are not cytotoxic up to 10 mol% of the BaO.

Acknowledgments:CNPq and CAPES for financial support of this study.

Titanium coating with calcium titanate by sol-gelmethod: the influences of calcium amount and temperature

Júlia Bucci[1], Maria Gabriela Jacheto Carra[1], Margarida Juri Saeki[1]

[1]Instituto de Biociências de Botucatu - UNESP (*1 Department of Chemical and Biological Sciences*)

e-mail: j.bucci@unesp.br

Bioceramics have been considered as a component of devices for bone fractures and defects correction, as they provide good adsorption and cell growth. Because of these properties, they are used as surface coatings on metallic implants. Calcium titanate stands out because it promotes apatite precipitation and optimizes bone fixation time to the titanium [1]. Also, it can be applied in association with hydroxyapatite. The objective of this work is to prepare calcium titanate films on titanium and studying the influences of calcium amount and temperature on the crystalline structure, crystallinity of films and surface charge. Samples of commercially pure titanium (cp-Ti., ASTM F67 GR2) were polished and treated with diluted hydrochloric acid. Sols with Ca:Ti molar ratio of 1:2, 3:4, 1:1. The titanium plates were coated by dipping into the sols, hydrolyzing under atmospheric humidity and heat treating in the temperatures between 400ºC and 600ºC. The samples were submitted to two characterization techniques: X-Ray Diffraction (XRD) and Surface Zeta Potential measurements. XRD analysis showed that the presence of crystalline calcium titanate (PDF: 42-423) was more evident when the films were prepared in a 3:4 ratio and calcined at 600°C, indicating that the preparation method used is effective to coat the titanium with calcium titanate. The study of surface zeta potentials indicated that both the variation in molar concentrations and temperature influenced the surface charges This study allowed to identify the characteristics of the surfaces as a function of synthesis conditions, which will be useful to choose the adequate methods to deposit on the modified substrate.

(Cancer) Theranostics with (Intrinsically) Radiolabeled Nanomaterials

Weibo CAI[1]

[1]University of Wisconsin – Madison (*Radiology, Medical Physics, Materials Science & Engineering, Pharmaceutical Sciences*)

e-mail: wcai4@wisc.edu

Radiolabeled nanomaterials have gained tremendous interest over the last 2 decades, which can play diverse roles in imaging, image-guided drug delivery, as well as theranostics of a number of diseases such as cancer. Some recent examples of radiolabeled materials from our recent work will be briefly described in this talk.

Although chelator-based radiolabeling techniques (commonly used for labeling nanomaterials with radiometals such as ^{64}Cu/^{89}Zr) have been used for decades, concerns about the complexity of coordination chemistry, possible alteration of nanomaterial pharmacokinetics, and potential detachment of radioisotopes have driven the need for developing a simpler yet better technique for future radiolabeling, which may facilitate future clinical translation.

The emerging area of intrinsically radiolabeled nanomaterials can take advantage of the unique physical and chemical properties of well-selected inorganic or organic nanomaterials for radiolabeling, and more importantly, offer an easier, faster, and more specific radiolabeling possibility to facilitate future clinical translation. Generally speaking, the four major categories of intrinsically radiolabeled nanomaterials include: 1) hot-plus-cold precursors, 2) specific trapping, 3) cation exchange, and 4) proton beam activation.

Representative examples of these strategies will be briefly illustrated in this talk, with the main focus on our own work that involves the radiolabeling of a variety of nanomaterials via “specific trapping”. The nanomaterials investigated in our laboratory include silica/carbon-based nanomaterials, COVID-19 nano-vaccines, multifunctional/multimodal hybrid nanomaterials, iron oxide nanoparticles, micelles, DNA nanostructures, etc.

Invited Speaker: Shedding Light on Ag2S Nanoparticles: Imaging, Sensing, and Beyond

Erving Clayton Ximendes[1], Daniel Jaque[2]

[1]Universidad Autónoma de Madrid (*Física de Materiales*) , [2]Universidad Autónoma de Madrid (*Fisica de Materiales*)

e-mail: erving.ximendes@uam.es

The use of luminescent nanoparticles for imaging and therapeutic purposes has gained significant attention in recent years. In this study, we present experimental data both on sensing capabilities as well as the pharmacokinetics of Ag2S nanocrystals of varying sizes, charges, and surfaces. These nanoparticles can be excited in the first near-infrared window and emit in the second, making them a promising candidate for biological applications. Our results show different patterns of distribution and a wide range of applicability for targeted imaging strategies. These findings could pave the way for the development of new imaging tools and therapies using Ag2S nanocrystals.

Nanoparticle-mediated immune suppression ofmetastatic cancer

Preethi Korangath[1], Lu Jin[2], Chun-Ting Yang[1], Sean Healy[1], Chen Hu[1], Suqi Ke[1], Kathlene Gabrielson[1], Jeremy Foote[3], Robert Clarke[2], Robert Ivkov[4]

By virtue of size and coating, nanoparticles interact with innate immune cells. These interactions can stimulate immune signaling to initiate adaptive immune responses. Here, we explored such a potential shown by iron oxide nanoparticles coated with hydroxyl ethyl starch using transgenic and syngeneic metastatic breast cancer mouse models. Mouse models comprised Human HER2 overexpressing transgenic mice (HuHER2 in FVB/N background) that spontaneously develop primary breast tumors and lung metastasis (40-50%); and, orthotopic implanted Py230 cells growing in C57BL/6 mice that also spontaneously metastasize to lungs (30-40%). Tumor-bearing mice injected intravenously with Bionized Nano ferrite nanoparticles (BNF) at a non-toxic, human equivalent dose of 5mgFe/mouse into their tail vein displayed significant inhibition of tumor growth and complete inhibition of metastasis. In depth molecular analysis showed that the Toll Like Receptor (TLR) pathway mediated immune signaling was altered by BNF mostly in tumor and in nanoparticle associated cells collected from all analyzed tissues. BNF activated TIR-domain-containing adapter-inducing interferon-β (TRIF) culminating in phosphorylation and translocation of Interferon Response Factor 3 (p-IRF3) to the nucleus. This in turn activates interferon-β mediated antiviral response resulting in T cell stimulation. Requirement of TRIFin demonstrating anti-tumor immune effects was confirmed using TRIF knockout mice which displayed a complete reversal of primary tumor growth inhibition by treatment with BNF. These findings open a new direction to explore iron oxide nanoparticles as immune modulators with anticancer effect and their potential as TLR3 agonists for treating metastatic breast cancer.

Surface modification of nanoparticles: disguise, blendin or stand out?

ELIANA MARTINS LIMA[1]

e-mail: emlima@ufg.br

Several approaches to circumvent issues related to liposomes stability, circulation time or biointeractions are based on membrane surface modifications, being PEG the most widely used. However, PEG is also linked to a number of unwanted outcomes, such as accelerated blood clearance and other adverse reactions. We hypothesize that biomimetic liposomes, incorporating cell membrane derived components enriched with synthetic lipids might be a promising approach for specific nanomedicine applications. We have prepared biomimetic vesicles by combining specific cell membranes (erythrocytes or tumor cells) with synthetic or purified phospholipids using freeze-thaw cycles and extrusion protocols. Membrane properties and lipid dynamics were characterized by biophysics assays (EPR) and their performance was measured in vitro and in vivo (tumor murine model). Biomimetic hybrid liposomes present biophysical properties directly modulated by their synthetic lipid content. Biomimetic vesicles prepared with tumor cell membranes are able to induce immune response in mice following different cancer vaccination protocols leading to a reduced number of metastasis and increased animal survival rates. Biomimetic nanocarriers combining synthetic or purified phospholipids and different cell membranes into a hybrid nanovesicle can exhibit controllable properties derived from the biomembrane (such as self-markers and other proteins) and from added lipids, opening several possibilities for tuning specific features. These systems are excellent candidates as a nanomedicine platform since the insertion of purified or synthetic lipids in their preparation is one additional step towards scalability and reproducibility.

ANTIANGIOGENIC AND ANTITUMORAL ACTIVITY OF BIOMIMETIC DELIVERY SYSTEMS USING THE CHICKEN CHORIOALLANTOIC MEMBRANE (CAM) ASSAY

e-mail: noronhanat@hotmail.com

Glioblastoma (GBM) is a prevalent malignant brain tumor with a high recurrence and mortality rate, with an overall median survival rate not longer than two years1. The limited prognosis of GBM is usually related to tumor heterogeneity, drug resistance, and insufficient brain drug delivery, as a result of the restricted access to the tumors imposed by the blood-brain barrier (BBB)2. In this regard, engineered biomimetic nanosystems have overcome important shortcomings over conventional therapy, providing significant features, especially in terms of therapeutic activity3. Here, we hypothesize that a biomimetic nanostructured delivery system based on polylactic/glycolic acid (PLGA) for temozolomide (TMZ) encapsulation should provide significant improvements in therapeutic outcomes regarding the antiangiogenic and antitumoral activity. Therefore, the U251 glioma cells (2x106 cells) were implanted into the CAM using maxgel support to perform a tumor mass. Tumor area and perimeter measurements were carried out before and after treatment and the CAMs with tumors were excised and imaged for blood vessel quantification. Our results indicate the antiangiogenic potential and tumor reduction due to biomimetic nanosystems treatment. This strategy may represent a potential treatment for GBM in future clinical applications improving therapeutic outcomes.

e-mail: isabelabessa@id.uff.br

Mesoporous silica nanoparticles (MSN) have been explored in biomedical field due to the possibility of trapping molecules within their ordered pore channels. Our research group have been already exploring this material using it as a nanoreservoir in the development of nanovalves for cancer treatment[1]. Because MSN structure is very stable, hydroxyapatite (HAP) can be incorporated into its structure aiming to improve MSN biodegradability and biocompatibility by enhancing MSN solubility in acid environment. Here, we propose two different biocompatible materials based on mesoporous silica and hydroxyapatite by using two different synthetic procedure [2,3]. Both biomaterials were compared with pure MSN. The first biomaterial, named MSN-HAP, displayed separated phases, in which MSN had a smaller size than pure MSN (50 versus 100 nm) and HAP presented an elongated shape. The second material, named HAP@MSN, showed a core-shell structure, where the MSN phase formed a shell around HAP phase. Also, the biomaterials presented similar BET specific areas and drug loading, but different pore arrays, without the hexagonal porous structure commonly observed for MSN. This fact was directly translated on DOX kinetic release behavior. The porous disorganization provided to the materials MSN-HAP andHAP@MSN a lower DOX release profile in comparison to pure MSN, at pH = 4.5, which is desirable for drug delivery systems. Moreover, as a result of the presence of HAP in a separated phase, MSN-HAP showed the lowest release because HAP particles could practically block the pores, hampering the drug release. In vitro studies against esophageal cancer cells TE-1 are being performed.

Iron oxide-based nanoparticles have several clinical applications, such as anemia treatment, MRI contrast agents and magnetic hyperthermia. In this presentation we investigate the theranostic applications of membrane-coated magnetic nanoparticles. Distinct cell membranes are used for surface coating the nanoparticles namely erythrocyte, B16F10 (melanoma), 4T1 (breast cancer) and GL261 (glioblastome). Two magnetic nanoparticles are investigated, maghemite and Mn-ferrite. Nanoparticles were characterized by several techniques (TEM, XRD, NTA, DLS, VSM, among others). Distinct magnetic nanocarriers are prepared and their properties for thermal nanomedicine compared namely magnetic fluids, magnetoliposomes, magnetic hybrid liposomes, and biomimetic magnetic vesicles. T1 and T2 magnetic resonance imaging agent properties are obtained with a 1T MRI pre-clinical equipment. For some vesicle samples we also added IR-780 dye in the membrane for near-infrared imaging applications. Magnetic hyperthermia (MH) and photothermal therapy (PTT) data are reported at clinically relevant experimental conditions. We obtained the nanocarriers photothermal conversion efficiency parameter and demonstrate that the photostability depends on nanocarrier design. Preliminary results of MRI thermometry using the PRF method and the potential of IR-780 for luminescent thermometry during PTT are also reported. The data indicates that the biomimetic magnetic nanocarriers have great potential for cancer therapy.

Buffering effect of cell membrane-coated ZnOPEI nanoparticles on pancreatic cancer under hypoxia conditions

e-mail: bianca_estevao@hotmail.com

Some cancers can lead to malignant progression and metastasis if diagnosed late. Advanced-stage tumors are highly vascularized but unbalanced, and in this case, the cells grow rapidly and undergo anaerobic respiration [1]. As a result, high concentrations of lactate are produced and the pH of the medium is lowered, known as tumor hypoxia condition [2]. Highly basic molecules/polymers (Polyethylenimine - PEI) can destabilize tumor metabolism, leading to tumor mass reduction and/or steady progression. In this study we focus on the synthesis of organic-inorganic positive hybrid nanoparticles vectorized using liposomes or real membrane, for action in the hypoxic tumor environment. The ZnO quantum dots was synthed by sol-gel methodology with their surface modified using GPTMS crosslinking with PEI polymer being developed a luminescent cluster nanoparticle with a compelling buffering characteristic. The buffering effects was confirmed by tritation carrying between 12 - 2 pH, showing two effects, first with protonation of NH2 groups of PEI and then with degradation of ZnO-GPTMS. Interestingly, ZnO degrades at low pH, being a possible hypoxia biomarker. The use of liposomes coated with biotin-modified F127 proved to be efficient in internalization and also showed greater stability than conventional liposomes. We also developed a nanoparticle covered with a real cell membrane (PANC-1 cell membrane), revealing a potential nanovector for application in personalized medicine. In this case, we performed for the first time an evaluation of the buffer effect on lactate inthe cells, ROS generation, and cell death. Our studies showed that cell viability decreased atlow concentrations and that the ROS production and intracellular lactate storage were dose-dependent and triggered cell apoptosis.

Cell-Penetrating Peptide Nanotechnology: Opportunities in the Development of InnovativeTherapeutics

Emerson Rodrigo da Silva[1]

[1]Departamento de Biofísica, Escola Paulista de Medicina, Universidade Federal de São Paulo

e-mail: er.silva@unifesp.br

Cell-penetrating peptides (CPPs) are bioactive molecules envisaged for the future development of nanotherapies. These peptide sequences, usually constituted by short strands of amino acids ranging from 5 to 30 residues, exhibit a strong ability to translocate through biomembranes, making them ideal candidates for the production of non-viral vectors in various applications, including gene therapy. In this communication, I will present recent studies carried out in our laboratory on the structure of DNA vectors based on CPPs that explored the design, characterization, and cell interaction of synthetic CPPs[1-3]. The structural features of different classes of CPPs will be highlighted, with special attention to hydrophobic CPPs that exhibit low cytotoxicity and high amyloidogenic propensity. Advanced methods of structural characterization of these systems will be discussed, with a focus on high-resolution small-angle scattering and AFM-based infrared spectroscopy. A special focus will be given to the need for interdisciplinary research at the interfaces of Physics, Chemistry, and Biology for the future development of peptide-based nanotherapy. Finally, the consequences of using these materials in the creation of new advanced materials will be highlighted, with examples pointing to future directions of development.

CELLULOSE NANOCRYSTALS FOR ANTICANCER DRUG DELIVERY

Alessia Sambugaro[1], Marina Scarpa[2], Chiara Nardon[3], NICOLA DALDOSSO[1]

[1]University of Verona (*Engineering for Innovation Medicine*) , [2]Università degli Studi di Trento (*Physics*) , [3]University of Verona (*Biotechnology*)

e-mail: alessia.sambugaro@univr.it

Compared to conventional therapeutics in cancer treatment, nanoparticle-based drug delivery has specific advantages, such as the ability to transport and release a high quantity of drug to a precise target, an improved stability and biocompatibility, enhanced permeability and retention effect, good pharmacokinetics and a role in overcoming cancer-related drug resistance. Among the several nano-systems under investigation for drug delivery, cellulose nanocrystals (CNCs) offer interesting opportunities as innovative nano-carriers in the oncological field for their versatility, easy tunable surface according to the nature of the loaded drugs. Moreover, they are suitable for clinical use thanks to their biocompatibility and biodegradation. Cellulose nanocrystals (CNCs) were made by an easy procedure wherein carboxylic groups are introduced into never dried cellulose pulp by oxidation at alkaline pH using 2,2,6,6-tetramethylpiperidine-1-oxyl radical (TEMPO) as a catalyst, followed by dialysis and autoclave sterilization. At the end of this procedure, a transparent suspension of rod-like CNCs is obtained. The obtained size is rather independent on the plant source and it is well known to fit in the range 3-5 nm of width and 200-500 nm of length. After the physical characterization by TEM (Transmission Electron Microscopy), DLS (Dynamic Light Scattering), and AFM (Atomic Force Microscopy) to investigate the morphology and the size, the carrier was loaded with anticancer drugs (e.g. doxorubicin). Drug release was studied in PBS (phosphate buffer saline) and water solution and resulted in an efficient release rate.Moreover, their cytotoxicity was evaluated in vitro on human cancer cell lines (prostate and lung cancer cells, i.e., PC3 and A549, respectively) and compared to the corresponding free drug.

Cubic phase nanoparticles in the presence of lysozymeand curcumin: A structural approach

e-mail: heidie.torres@lnls.br

The study of drug delivery systems has gained much attention in recent years due to the advantages of using such systems, such as the possibility of controlling the amount of drug delivered to the recipient organism. Cubic lipidic nanoparticles, known as cubosomes, show promise within this perspective. This work aims to investigate physical characteristics as , concentration, and structure of cubosomes, encapsulating lysozyme and curcumin in different regions of this nanoparticle. Small Angle X-ray Scattering (SAXS) data were obtained at MAX IV synchrotron, while Dynamic light scattering (DLS) and Nanoparticle Tracking Analysis (NTA) data were obtained at LNLS/CNPEM. Also, a cell viability test was made, to obtain the drug''s activities against human breast cancer cells (MDA-MB-231) and human epidermal keratinocyte (HaCat). DLS and NTA results show that these cubosomes have an average of 200(2) nm, and an average concentration of 1.00(3)x1012 part/ml. SAXS curves show that the inner cubic structure of cubosomes is kept unaltered in the presence of increasing lysozyme and curcumin concentrations. Cell viability test show promising results for all the dosages in both cells, up to 70%. In short, our work intends to provide a study of structural and functional characterization about this system, and further, other analysis will be made to achieve them.

e-mail: rs.vianarodrigo@gmail.com

Porous nanomaterials (PN) acting as drug delivery system have gained prominence in recent years Several types of PN acting as vehicles have been described, including compounds based in Zeolitic Imidazolate Framework-8 (ZIF-8) and its composites [1]. Urs-12-ene-3,28-diol (uvaol), has been one of the most interesting natural drugs due to its relevant inhibitory activity, effects on antigen-induced lung inflammation that are shown to be potentially useful for treating Chronic Obstructive Pulmonary Disease (COPD) [2]. In this work, a luminescente drug delivery nanocomposite based on the porous ZIF-8 combined with a Europium complex (EuTTA) to obtain the **EuTTA/SiO_2/ZIF-8**was used for uvaol release. XRD for **EuTTA/SiO_2/ZIF-8**showed characteristic planes of the ZIF-8 (I-43m space group) corresponding to the crystallographic data [3]. FTIR spectra revealed the signals: C=N (1520-1290 cm^{-1}), asymmetric (1601 cm^{-1}) and symmetric (1403 cm^{-1}) νCOO^-stretches from the imidazole ligand and the EuTTA complex, respectively. In addition, the emission spectrum revels the caracteristic f-f transitions$^5D_0 \rightarrow {}^7F_{0-4}$from Eu^{3+}ion, which are analogousto isolated EuTTA. Uvaol release assay was performed in PBS pH = 7.4 and revealedthat **EuTTA/SiO_2/ZIF-8**achieves rapid release (≈ 52%) after 8h. In addition, MTT assay using J774 macrophages showed viability greater than 85%. In short, the recent results obtained indicate that **EuTTA/SiO_2/ZIF-8**presents itself as a promising platform for use as avehicle for drug delivery of uvaol.

Development and characterization of chitosan nanoparticles loaded with different aminoglycoside antibiotics

Cecilia Zorzi Bueno[1], Tainá Kleinubing Da Silva[1], Helton José Wiggers[2], Pascale Chevallier[3], Francesco Copes[4], Diego Mantovani[5]

[1]Associação de Ensino, Pesquisa e Extensão Biopark, [2]Associação de Ensino, Pesquisa eExtensão Biopark (*LBB-BPK*) , [3]Université Laval (*CR-CHU de Québec*) , [4]Université Laval, [5]Université Laval (*Lab Biomaterials and Bioengineering*)

e-mail: cecilia.bueno@bpkedu.com.br

Chitosan is a biodegradable and biocompatible polymer that has large potential for biomedical applications, particularly in the nanomedicine field, for the development of drug delivery systems. Besides other applications, chitosan nanoparticles (CS NPs) can be used to encapsulate drugs, promoting sustained release, improving drug bioavailability and stability [1].

This study consisted of developing and characterizing CS NPs loaded with two broad spectrum aminoglycosides, gentamicin or tobramycin. Chitosan-gentamicin (CS-G NPs) and chitosan-tobramycin (CS-T NPs) nanoparticles were obtained by dropwise addition of an aqueous solution of tripolyphosphate to a mixture containing chitosan and antibiotic at 60% of the chitosan weight, under magnetic stirring. The systems were centrifugated at 3500 rpm to remove agglomerates. The release behaviour was performed in PBS at 37ºC, and the antibacterial activity against gram+ and gram- strains was assessed by Kirby-Bauer tests.

The results showed that CS-G NPs and CS-T NPs had average sizes ranging from 120-160 nm and 130-160 nm, and encapsulation efficiencies from 40-75% and 60-75%, respectively. Polydispersity index was around 0.2 for both systems. In addition, they were both found to be antibacterial against the bacteria tested. After a continuous release for 2 hours, the kinetics seemed to depend on the encapsulated antibiotic. Indeed, while CS-G NPs released a maximum of 70% of the incorporated antibiotic, CS-T NPs released only 55%. The higher retention of tobramycin may result in a more controlled and prolonged release system compared to CS-G-NPs.

In conclusion, CS NPs encapsulating different aminoglycosides were successfully obtained through a simple approach, which has not yet been fully explored in literature. CS-T NPs can be considered promising systems for long-term sustained release.

Prostate Cancer (PCa) is one of the most commonly diagnosed malignant diseases in men around the world. Even with recent advances in the treatment of PCa, 40% of patients with local tumors develop metastasis [1]. The application of gold nanorods (AuNR) associated with Brazilian red propolis (BRP) can be an effective therapeutic alternative in the treatment of CaP, by associating chemotherapy with phototherapy. BRP is known for its anti-inflammatory and antitumor properties. The aims of this work were the development of a formulation composed of AuNR associated with extracellular vesicles (EVs) and BRP and their biological evaluation in prostate cancer cells. AuNRs were prepared by seed formation method and functionalized with thiol polyethylene glycol (PEG-SH). For association of AuNR-PEG with EVs and BRP a sonication method was used. The final dispersion showedtwo absorbance bands measured by UV-Vis, the largest one at 760 nm. AuNR-PEG-EV-BRPwere characterized by Transmission Electron Microscopy showing an aspect ratio of 3.2 ± 0.8. Hydrodynamic diameter (163.2 ± 21.8 nm) was obtained by Dynamic Light Scattering and Nanoparticle Tracking Analysis. Zeta potential value was negative. Biological studies were performed using prostate normal (PNT-2) and prostate cancer cells (PC-3 and LNCaP). The viability assays were carried out in the absence and presence of NIR light. The results demonstrated an enhanced antitumor effect after the system was irradiated using NIR laser (808 nm). Moreover, viability assays in normal cells showed low cytotoxicity. These results suggest the potential application of AuNR-PEG-EV-BRP in cancer therapy.

DOPED CARBON NANOPARTICLES AS AGENTS FOR ANTI-CANCER THERAPY

The search for new therapeutic approaches for cancer is important since current resources are still insufficient. One option is Photodynamic Therapy (PDT), which generally acts by leading to the formation of reactive oxygen species due to the transfer of energy to photosensitizing molecules (PS) upon exposure to a beam of light. However, the use of conventional FS agents is limited due to the low penetration of light and the low diffusion of these agents to tumor cells. In this context, nanotechnology emerges as a potential solution to issues of improving the efficiency of PDT, where carbon nanoparticles (NPs) have been applied in several recent types of research. The present work sought to investigate the behavior and stability in the biological environment of carbon NPs doped with Nitrogen (N-GOQD), Boron (B-GOQD), and Phosphorus (P-CND), as well as their cytotoxic activity in neoplastic cells, to that these can be applied and/or modified for the application in GT. The characterization of the particles by transmission electron microscopy image indicated that these particles present little variability in their size and shape. To understand the behavior of NPs in a biological environment, assays were carried out to assess in vitro cytotoxicity (MTT assay) using neoplastic cells of the macrophage lineage J774.G8. In 24h of exposure and with increasing concentration, B-GOQD has the highest cytotoxic potential. When compared, N-GOQD and P-CND did not show significant cytotoxicity against the J774.G8 strain. Preliminary tests for the evaluation of the uptake of NPs by the cells show that, in 4h of exposure, about 10% of the concentration of P-CND particles are captured or deposited on the surface of the cells. The characterizations carried out on the carbon NPs applied in the present work bring important information about their physicochemical and biocompatibility properties, however, there is still a need for additional tests to obtain a good photosensitizing agent

Electrically conductive polyaniline-derived nanofibers as active interface for biomedical applications

Arthur Henrique Vidigal De Miranda[1], Jéssica Cavaleiro da Silva[1,2], Anna Lecticia Martinez Martinez Toledo[1], Giovanni Vita[2], Carlos Augusto Gomes Soares[2], Paulo Henrique de Souza Picciani[1]

Polyaniline and poly(lactic acid) (PLA) blends are considered a promising combination for biomedical applications involving electrical challenges and impedance determination. Nonetheless synthesizing these polymer blends require the use of novel strategies [1]. In this work, polyaniline (PANI) and its derivatives poly(o-methoxyaniline) (POMA) and poly(o-ethoxyaniline) (POEA) were chemically synthed using an ultrasonic method. The synthed polymers were doped with p-toluene sulfonic acid and electrospun as blends with PLA, originating fibers of approximately 100 nm in diameter for all groups. Physicochemical and thermal properties were assessed by TCA and DSC analyses. The structural features of each membrane composite were also compared by XRD, FTIR, SEM and ElectrochemicalImpedance Spectroscopy (EIS) to determine their charge transport behaviors. The biocompatibility of the nanofibers was evaluated by in vitro tests with the human triple-negative breast adenocarcinoma MDA-MB-231 cell line and cytotoxicity assays using SYTOX™ Green dye for live/dead cells quantification and flow cytometry analysis. Taking all together, PLA/POMA membranes demonstrated the best electrical properties, with adequatein vitro biocompatibility. All tested nanofibers preserved ~ 90% of cell viability after 48 h incubation with MDA-MB-231 at 37°C/5% CO2, similar to controls. Our results present thePLA/POMA blend as a promising matrix with broad medical potential, as for the use in liveimpedance measurement strategies and/or for specific electric potential protocols for therapeutic purposes [2].

Nanotheranostics is a powerful combination of diagnosis and imaging through nanoparticle systems. In this work, gluthatione capped silver sulfide quantum dots (Ag_2S-GSH QDs) are studied with the objective of promoting the diagnosis of tumors by fluorescence and treatment by photothermia. Ag_2S QDs were synthed via electrochemistry using a cavity cell,[1] where the optical properties of the nanocrystals were modulated by changing the molar ratio $Ag^+/HS^-$and the heat treatment. The nanocrystals present optical emission in the near infrared region, at wavelengths ranging from λem = 735 - 916 nm for the proportions1:1 and 1:4 (Ag^+/HS^-), respectively. The nanocrystals had an average diameter ranging from 4.2 nm to 5.5 nm, with a monoclinic crystalline structure [2]. When Ag_2S QDs were irradiated with laser in the near infrared region (λexc = 785 nm) they showed a photothermal response, ranging from 27 ºC for Ag_2S (6:1 ratio) to a maximum of 39 ºC (1:1 ratio) when covered with zinc selenide seeds (Ag_2S@ZnSe). MTT tests for HT29 cell line were performed, showing no toxicity, according to ISO 10993-5:2009. (Biological evaluationof medical devices: Tests for in vitro cytotoxicity i.e., cell viability >70%). The proposed system represents a green path to produce promising nanomaterials for application in nanotheranotics, through the electrochemical route and compositional engineering, combining a lower environmental impact with increased system efficiency.

Photodynamic therapy (PDT) is an alternative treatment for cancer. However, it is limited to tumors accessible with a laser in the UV-Visible region (active region of photosensitizers (PS)), the molecule responsible for cell death after its activation with a light source). Still, this energy range has low penetration into biological tissues. To extend the PDT to non-superficial tumors, we propose the development of fluoro-perovskite nanoparticles with upconversion (UC) properties, which will allow access to the PS (Aminolevulinic acid) to the inner tumor cells. UC enables the transformation of photons from the IR region (greater penetration of biological tissue) to the active region of the photosensitizer (405 and 635 nm), reaching non-superficial tumors. The UC property is achieved by incorporating dopants (rare earth and transition metals) into the nanoparticles. We investigated the solvothermal synthesis of $KMgF_3$nanoparticles through a rational design. Using statistical tools, we evaluated the influence of parameters such as precursor concentration, time, temperature, and dopant level obtaining nanoparticles with optimal properties for PDT. The statistical analysis yielded that the variable temperature and the interaction of temperature with the concentration of $MgCl_2$have a significant effect on the particle size, and that 14 of the experimental conditions did not present significant differences in particle size for a significance level of 0.05. Additionally, $KMgF_3$nanoparticles were doped with different concentrations of Nd^{3+}, Mn^{2+}, and Nd^{3+}/Mn^{2+}. The nanoparticles' optical properties were evaluated, confirming the upconversion process for samples with the highest concentration of $Nd^{3+}$and Mn^{2+}. Advances in this topic allowed us to move forward to the next steps involving functionalization and bioassays to evaluate the potential application of $KMgF_3:Nd^{+3}/Yb^{3+}/Mn^{2+}$in PDT.

Exploring the Role of Glycocalyx and Protein Corona inthe Cellular Uptake of Silica Nanoparticles

Paulo Henrique Olivieri Junior[1], Isabela Ferreira Assis[1], Helena Bonciani Nader[2], Giselle Zenker Justo[2], Alioscka Augusto Sousa[1]

e-mail: pho.junior@unifesp.br

Engineered nanoparticles (NPs) have remarkable potential for diverse biomedical applications. Over the last few decades, numerous studies have focused on characterizing and understanding the biointeractions of NPs with cells, especially factors that affect cellular internalization of particles. However, predicting or explaining specific outcomes remains challenging due to the complex nature of NP-cell interactions and endocytic processes. One the one hand, the formation of an adsorbed protein corona around NPs is a critical factor that influences NP-cell interactions and endocytosis. In addition, when NPs approach the cell surface, they first encounter the glycocalyx (GCX), a negatively charged glycosaminoglycan (GAG)-rich layer attached to the plasma membrane. Recent studies have suggested that the GCX may play an important role in regulating endocytosis, as it can either hinder or facilitate the process, depending on both the NPs'' and GCX’ s characteristics. However, interactions between the protein corona and the GCX and their impact on NP uptake remain poorly understood. Recently, our group investigated how the GCX modulates the cell uptake of charged NPs in the absence of a protein corona. In the present study, silica NPs were covered by well-defined coronas of albumin (BSA), cationized albumin (BSA+) and fetal bovine serum (FBS). The NPs were exposed to wild-type and GAG-mutated CHO cells and uptake was quantified by flow cytometry. Additional cell uptake experiments were performed using wild-type cells in the presence of glycolytic enzymes or chemical/pharmacological inhibitors. Furthermore, biophysical measurements were performed to understand the interactions between the protein coronas and free GAGs. We found that free GAGs bound not only to BSA+ coronas, as expected, but also to BSA and FBS coronas despite their negative zeta potentials. Surprisingly, CHO cells containing intact GAGs showed enhanced NP uptake for all coronas.

Illuminating the Biological World through Infrared Radiation at IMBUIA Beamline on Sirius

Ohanna Maria Menezes Madeiro da Costa[1], Raul O. Freitas[1,2]

[1]Brazilian Center for Research in Energy and Materials (*LNLS*) , [2]Centro Nacional de Pesquisa em Energia e Materiais (*Laboratório Nacional de Luz Síncrotron*)

e-mail: ohanna.costa@lnls.br

IMBUIA Beamline (Microspectroscopy and Infrared Imaging) is an advanced facility dedicated to the study of materials at molecular and nanoscale levels. With its high brightness, it offers synchrotron-based infrared spectroscopy and imaging techniques, allowing researchers to explore the molecular and vibrational properties of samples with exceptional sensitivity and spatial resolution. The use of infrared radiation (IR) in the investigation of biological systems has proven to be a valuable tool to analyze the molecular composition, structure and dynamics of samples without the need for chemical markers. For example, it can detect DNA damage in fungi exposed to volatile organic compounds, using the natural molecular vibrations of the samples. IR spectral microscopy provides chemically specific information with spatial resolution, allowing researchers to map the distribution of specific biomolecules within tissues and cells. Infrared imaging has proven particularly useful in cellular research as it facilitates the characterization of local chemical variations and the identification of specific components within complex systems. By integrating spatial and spectral information, the composition and distribution of materials in biological, geological and materials science research is revealed. The versatility of the IMBUIA Beamline, with its synchrotron-based infrared microspectroscopy and imaging capabilities, offers powerful opportunities to delve into the molecular world and gain a deeper understanding of material properties. The application of IR in the study of biological systems offers benefits such as characterization of biomolecules, spatial imaging, probing interactions and changes and dynamic analysis without relying on chemical markers. These applications will significantly advance our understanding of the biological world and drive technological progress in infrared spectroscopy.

e-mail: claralbf@gmail.com

Nanotechnology has been increasingly investigated as a promising strategy to address the growing challenge of antimicrobial resistance [1]. Nevertheless, the current understanding of the interaction mechanisms between nanoparticles (NPs) and bacteria remains limited, largely due to the spatial resolution constraints of conventional surface characterization techniques, as Fourier transform infrared (FTIR) and Raman spectroscopies [1-2]. The aim of this work is to monitor the surface interaction between *Escherichia coli* (*E. coli*) and silica-based NPs (SiO_2NPs) coated with carbohydrates, using a cutting-edge approach that combines Scanning Near-field Optical Microscopy (s-SNOM) with broadband synchrotron infrared nanospectroscopy (nano-FTIR). To enhance the interaction between the NPs and the bacterial membrane at the nanoscale, SiO_2NPs were coated with the carbohydrates mannose, maltose or trehalose, since Gram-negative bacteria are known to recognize and interact with glycans [3]. Physical-chemical characterization techniques were performed in order to confirm the presence of carbohydrates, and the interaction between NP's and bacteria were studied by biological *in vitro* assays and scanning electron microscopy. Moreover, the resulted carbohydrate-functionalized SiO_2NPs were evaluated for colloidal stability in several media. This work presents a unique approach for studying the nano-bio interface using the Nano-FTIR technique, which enables the chemical and morphological analysis of a single cell''s surface with a remarkable spatial resolution of 30 nm. This advanced capability was made possible by the Imbuia-Nano beamline at Sirius in Campinas.

e-mail: bismarck1989@gmail.com

Multifunctional nanosystems that combine magnetic and plasmonic properties are a promising approach for the development of new testing diagnosis devices due to the straightforward method for removal of the analyte from a complex matrix, in addition to the high sensitivity provided by surface-enhanced Raman scattering (SERS) [1-2]. In order to develop an approach for detecting diseases such as congenital adrenal hyperplasia, which is included in the routine screening of newborns, nickel ferrites ($NiFe_2O_4$) were synthed using the reverse micellar microemulsion method, following by their functionalization with cysteamine for being decorated with silver nanoparticles (AgNPs). Furthermore, the diffraction pattern shows the maximum profile of AgNPs, where an increase in peak intensity (111) was observed due to the high concentration of AgNPs on nickel ferrite surface, corroborating with SEM which shows a continuous layer of Ag on the nickel ferrite surface. According to VSM characterizations $NiFe_2O_4$ exhibited low coercivity, moderate saturation magnetization and low hysteresis losses, being classified in the soft ferrite class. To determine the chemical environment and oxidation state of the silver atoms on nickel ferrites, the samples were characterized by XPS at the central levels of 367.86 and 373.70 eV, assigned to Ag $3d_{5/2}$ and Ag $3d_{3/2}$, respectively. The potential of $NiFe_2O_4$–AgNP as a SERS substrate was demonstrated with methylene blue (MB) as target molecule. Therefore, magnetic plasmonic $NiFe_2O_4$–AgNP are promising for the development of biosensing tests as an alternative for routine analysis.

Mesoporous silica biomimetic nanoparticles for lung cancer therapy

ANGELICA MARIA MAZUERA ZAPATA[1], Valéria Maria Oliveira Cardoso[1], Valtencir Zucolotto[1]

[1]Universidade de São Paulo (*Nanomedicine and Nanotoxicology Group (GNano), São Carlos Institute of Physics*)

e-mail: anmazuera@ifsc.usp.br

Nanotechnology is an alternative to resolve the gaps in conventional treatments through designing drug delivery systems. The mesoporous silica nanoparticles (MSN) are proposed as a potential drug delivery for targeted non-small cell lung cancer therapy. These nanoparticles were synthesized by a co-condensation method and optimized employing physical-chemical treatments to use as nanocarriers of the chemotherapeutics drug carboplatin. The MSN showed different sizes and zeta potential depending on each treatment. Calcined MSN nanoparticles showed a diameter of ca. 88 nm, as observed by TEM microscopy and Pζ of -15.4 mV. MSNs functionalized with (3-aminopropyl)triethoxysilane (APTES) after-synthesis or treated with reflux, registered a diameter between 114 nm with Pζ of 35.2 mV, and 172 nm with a Pζ of 52.3 mV, respectively. The surface chemistry of MSN plays a vital role in the load and release drug, which was studied via MicroRaman and FTIR spectroscopy. In all MSNs spectra were observed transverse optical modes referring to the siloxane bond at 800 cm^{-1}(ν_s(Si-O-Si)$_{TO}$) and 1085 cm^{-1}(ν_{as}(Si-O-Si)$_{TO}$). The conversion between surface siloxanes and hydrogen-bonded silanols were observed for non-calcined nanoparticles, along APTES functionalized assigned same mode of the NH_2-CH_2-CH_2segment (shoulder at 1448 cm^{-1}) and bands observed for high Raman shifts corresponding to the connections between the $NH_2$and Si(-O-)$_3$. For the FTIR spectra, the vibrational modes of the ν(Si-O-Si) band were found at 1061 $cm^{-1}$and 1223 cm^{-1}, respectively. The Amine group was identified in the same region as Raman spectra for N-H stretching and bending mode. Non-calcined MSNs have a hydrophilic surface functionalized with APTES, which is more advantageous for drug delivery systems.

e-mail: gabizoia2002@gmail.com

Nanoparticles are promising drug delivery systems for many pathological conditions [1]. However, low targeting efficiency in vivo has been registered. A potential cause for this is that proteins spontaneously bind to the surface of nanoparticles when in biological fluids [2], forming a protein corona that affects the nanomaterial's properties, masking engineered functionality [3]. Therefore, to contribute to the development of more effective nanocarrier platforms, it is necessary to comprehend the formation of the protein corona and its consequences. Thus, this study is based on the investigation of the adsorption of human and bovine serum albumin (HSA and BSA) proteins onto silica nanoparticles of different s. Previous experiments using ultra-violet circular dichroism indicated that BSA may undergo structural rearrangement when bound to silica nanoparticles of approximately 170 nm. In order to explore the chemistry of the protein layer and evaluate possible conformational changes without the need for chemical labeling, two other techniques will be used: micro infrared spectroscopy with a microfluidics approach, and synchrotron infrared nano-spectroscopy.

Magnetic nanoparticles (MNPs) have unique properties that make them useful for biomedical and clinical research. They can be monitored using magnetic fields and detectors such as optically pumped magnetometers (OPMs). The National Institute of Standards and Technology (NIST) has developed chip-scale OPM sensors with sensitivities below 200 fT/Hz, which have been used in fetal magnetocardiography and magnetoencephalography studies. In a pilot study, MNPs were administered to male Wistar rats intravenously, and their distribution was monitored in real-time using a gradiometric array of QuSpin Total-Field Magnetometer (QTFM Gen-2) OPMs. The OPMs recordings allowed for the assessment of the arrival time of particles at the heart, their accumulation and subsequent emptying from the organ, and the determination of their circulation time. The results demonstrate the suitability of using OPM sensors for real-time detection of MNPs distribution and suggest a new possibility for evaluating their biodistribution. Future in vivo animal experiments are expected to use quantitative magnetic images to determine the passage of MNPs through the heart and hepatic uptake by the liver without external magnetization and without the need for a shielded room. The RNA delivery is emerging in the last century as a new class of therapeutic for a wide range of diseases. Delivering RNA is a very interesting strategy for cancer therapy and rare diseases,[1]but remains a great challenge because of its low cell uptake, instability in blood. For this reason, the use of lipidic nanoparticles has been recently witness as the solution for COVID 19 and the use of other type of nanocarriers is a promising approach for the RNA delivery and its controlled concentration over time. The problem is: what type of nanoparticles can be biocompatible, degradable and able to load enough RNA for therapeutic efficacy? Porous silicon nanostructures are of particular interest because of they fulfill all the requirements to allow in vivo applications, and they are easy to functionalize. The high porosity of these structure also allow a large amount of RNA entrapment and the structures prevent the degradation of the biomolecule and allow the specific drug release ina targeted area.[2]However, due to the fast degradability of the silicon, a coating with a polymeric layer is necessary to increase its stability and control the time of release. Here, we report a strategy to load a high amount of RNA and, to avoid its early release, the use of hyaluronic acid (HA) wrapped around the particles. The presence of HA also helps to be selective towards the tumor environment due to the presence of overexpressed CD44 receptors specific for the polymer. Also the release of the RNA is achieved by the HA degradation promoted by an enzyme called hyaluronidase.[3]In this work, is achieved a loading higher than 50% in weight thanks to the use of a calcium silicate reaction and we demonstrate the difference in the time release of RNA between nanoparticles coated and uncoated with HA.

THE PROCESSING OF CELL MEMBRANES AS ACTIVE MATERIALS FOR NANOCARRIERS FABRICATION AND THEIR APPLICATION IN PHOTO/CHEMO THERAPIES AGAINST CANCER

Valtencir Zucolotto[1]

e-mail: zuco@ifsc.usp.br

Recent advances in nanoengineering have allowed the isolation of both cell membranes (CM) and extacellular vesicles (EVs) to be used as efficient biomimetic nanosystems to deliver organic and inorganic molecules for cancer therapy. In this study we report the development of EVs and cell membrane-based nanocarriers encapsulating nanoparticles and anticancer drugs for both cancer photothermal and chemotherapies, respectively. Our results reveal a higher tendency of the EV-coated nanorods to interact with macrophages yet both EV- and cell membrane-coated nanorods were internalized in the metastatic breast cancer cells. Additionally, highly stable nanoparticles containing Gemcitabine (GEM), Paclitaxel (PTX), and Temozolomide (TMZ) were obtained using the major components isolated from tumor cell membranes. The nanoparticles containing GEM or PTX (NP-GEM-PTX) induced higher cytotoxic effects on pancreatic PANC-1 cells, in comparison to the use of pure GEM+PTX, indicating that membrane-covered nanoparticle favors the targeting and interaction with tumor cells. The biomimetic NP-TMZ system was built with isolated cell membrane from a U251 glioblastoma cell line and showed a greater affinity to U251 cells compared to other glioblastoma cell lines. The internalization of MNPs-TMZ in U251 cells was almost 2 times greater compared to U87 cells, and nearly 4 times greater compared to HCB151 cells. The use of EV- and cell membrane-coated nanoparticles opens up new possibilities regarding the development of efficient biomimetic nanosystems for cancer therapy and brings benefits to the field of personalized medicines.

2D and 3D spectroscopic studies, cellular uptake, and cytotoxicity assays of zinc phenyl-thio-phthalocyanine polymeric nanocapsules

Mariza Aires Fernandes[1], Ramon Botelho Costa[1], Fernando Lucas Primo[1]

[1]Faculdade de Ciências Farmacêuticas, Campus de Araraquara, UNESP (*Engenharia de Bioprocessos e Biotecnologia*)

e-mail: mariza.aires@unesp.br

Polymeric nanocapsules (NCs) are a drug delivery system consisting of biodegradable polymers and an oily core that acts as a reservoir and have attractive characteristics such as greater solubility, absorption, bioavailability of drugs and cellular specificity. The present work aims to determine the absorption spectrum (UV-Vis), fluorescence emission (2D and 3D) of free ZnS4pc and associated with polymeric nanocapsules (NC/ZnS_4Pc). In Vitro Biocompatibility and cellular uptake of NC/ZnS_4Pc in two types of normal human cell lines (HdFn and HaCaT). The NCs were prepared by the interfacial deposition method with anionic surfactant Kolliphor 188, PLGA copolymer (50:50) (poly (lactic-co-glycolic acid) (50:50)), soy lecithin, soy oil and ZnS_4Pc. To determine the absorption spectrum of free and associated ZnS_4Pc in nanocapsules in organic medium (acetonitrile and DMSO), spectroscopy studies (UV/Vis) were performed. Spectrofluorimetric analyzes were performed in 2D and 3D mode. Cytotoxicity and cell uptake study was conducted using different concentrations of NC/ZnS_4Pc in HdFn and HaCaT cell lines using the resazurin colorimetric method. The absorption and fluorescence emission spectrum (2D and 3D) of ZnS_4Pc and NC''s/ZnS_4Pc in organic medium showed similar profiles. In vitro cytotoxicity observed that NC/ZnS_4pc concentrations of 0.5, 1.0 and 2.0 µmol.L^{-1}showed no toxicity compared to the control for both cell lines tested. The concentration of NC/ZnS_4pc that demonstrated the best profile in the cell uptake assay was 2 µmol.$L^{-1}$for both cell lines tested. Photophysical characteristics at steady state did not change when carrying ZnS_4Pc in nanocapsules compared to free ZnS_4Pc. Therefore, the results obtained so far were considered promising for the next steps in 3D biological assays. This work was supported by FAPESP (The São Paulo Research Foundation), Grants M.A.F. nº 2020/09396-8 and CNPq Universal Project Grants F.L.P nº 404416/2021-7.

Acute Oral Toxicity Evaluation of CZIS/ZnS Quaternary Quantum Dots and Potential use as a Fluorescent Probe

Letícia Regina de Carvalho Cunha[1], Janaína Domingas Alves[1], Luana Caroline de Oliveira Lima[1], Paulo Henrique Almeida Campos-Junior[1], Marco Antonio Schiavon[1]

e-mail: leticia-rcc1@hotmail.com

Abstract: In vivo imaging is essential to identify cancer and increase patient survival. As an alternative to conventional techniques for monitoring tumors, in vivo imaging fluorescence has significant advantages, such as recognition of specific targets. As an attractive alternative to traditional fluorescent probes, quantum dots (QDs) have several advantages for biological analysis, such as, high quantum yields and excellent photostability [1]. There are countless possibilities for applying QDs in biological environments, but there is a lack of information regarding the effects generated in the short and long term. In this work, an acute oral toxicity test was performed for QDs CZIS/ZnS solubilized in phosphate buffer, according to Guideline 423[2]. The animals were divided into 3 groups formed by vehicle 300 mg/kg and 2000 mg/kg. They were evaluated for 14 days and then euthanized when their organs and blood were collected for further analysis. The highest dose showed 100% lethality, however, the 300 mg/kg dose showed no immediate effect, and no mortality. No side effects were observed in white and red blood series counts ($p>0.05$), as well as in relative organ weight ($p>0.05$), and estrous cycle duration ($p>0.05$). Therefore, CZIS/ZnS can be considered in category 4, according to the Globally Harmonized System of Classification and Labeling of Chemicals (GSH), with a Median Lethal Dose (LD50) >300-2000 mg/kg, revealing its very low toxicity. Altogether, these findings indicate that QDs CZIS/ZnS showed great potential to be used as a cellular probe and more studies has been done to validate its application.

Acknowledgments

Cystic fibrosis (CF) is a genetic disorder that affects the respiratory, digestive, and reproductive systems. Early diagnosis and treatment are critical for improving the quality of life and survival rates of CF patients. To facilitate early diagnosis, newborn screening programs have been implemented in many countries, which involve the collection of dried blood spots from newborns and subsequent analysis. However, current screening methods are expensive, invasive, time-consuming, and require specialized equipment and trained personnel, which limit their accessibility to remote areas where the neonatal screening program has no coverage. Currently, the most common strategy for CF diagnosis involves the determination of chloride concentration in sweat, as in case of a positive diagnosis the chloride concentration is over 60 mmol L-1.[1]

In this context, we developed polypyrrole-AgCl nanocomposites (PPy-AgCl-NC) which showed great potential for the development of electrochemical sensor for chloride. We investigated the chemical polymerization mechanism of pyrrole, in the presence of methyl orange, FeCl3 and different concentrations of silver nitrate, that allowed insitu formation of AgCl nanoparticles inside and outside of the polypyrrole structure depending on the concentration. The PPy-AgCl-NCs were characterized by scanning and transmission electron microscopies, showing the presence of polypyrrole nanostructures, and AgCl nanocomposites, respectively. When applied to chloride ions detection, the sensor demonstrated a remarkable faradaic response over a wide concentration range from 10 to 400 mmol L-1. Cyclic voltammetry was carried out in [Fe(CN)6]3-/4- solution to characterize the electrochemical parameters. This new approach holds promise for the diagnosis of CF and offers advantages in terms of low cost and reproducibility.

e-mail: jemmyson.jesus@ufv.br

The present study describes the synthesis, characterization (SEM, FT-IR, TGA, zeta potential, point of zero charge (pHPZC), and XRD), and in vitro study (delivery kinetics, membrane permeation, solubility isotherm, and toxicity) of a new smart nanocarrier based on magnetic nano-spheres (Fe_3O_4) functionalized with chitosan (CS) as a controlled release vehicle for CUR - (Fe_3O_4@CS-CUR) - for AD therapy. Characterization results showed that the synthesis and functionalization of the material occurred satisfactorily, as evidenced by FT-IR and TGA analysis. From SEM data, it was observed that the nanomaterial had an amorphous, irregular, and heterogeneous surface, containing iron nanoparticles impregnated on the surface of the chitosan polymer matrix, as evidenced by characteristic XRD peaks. The nanomaterial had an average size of 169 nm with a zeta potential of −30.7 mV. Fe_3O_4@CS-CUR presented a pHpzc at pH 8.0. The release study showed that at pH 7.4, the release of curcumin occurred in a controlled manner by the nanocarrier. Kinetic study indicated a second-order profile (R^2 = 0.96) for the delivering of CUR. Membrane permeation study on synthetic cellulose membrane (which simulated the blood-brain barrier) showed that Fe_3O_4@CS-CUR had satisfactory permeation, delivering CUR in a controlled manner. In the toxicity study, low toxic effects of the prepared nanocarrier were observed, with an EC50 (effective inhibitory concentration of 50%) of 554 µg mL-1. These data show that a new nanocarrier with potential application in AD treatment and low toxicity to cells has been successfully prepared.

e-mail: helinando.oliveira@univasf.edu.br

The selection of antibiotic-resistant bacteria requires the urgent development of alternatives to conventional antibiotics. With regard to skin lesions, several materials and treatments for injuries are already available. As a part of innovative therapeutic approaches against infections, Nile tilapia skin-based dressings present biological similar composition to human skin [1] and the reinforcement given by impregnation with silver nanoparticles due to their considerable antibacterial activity [2]. Herein, silver nanoparticles were reduced by the use of the extract of Ziziphus joazeiro, in association with zinc oxide, applied as an additive for the antibacterial activity of silver. The synthed silver nanoparticles and complexes of Ag and ZnO were characterized in terms of , zeta-potential and scanning electron microscopy as particles and after incorporation in Tilapia skin. The antibacterial activity was evaluated against Staphylococcus aureus and Escherichia coli with assays of zones of inhibition, kill time and biofilm inhibition. Reduction in the minimal bactericidal concentration was observed for samples prepared at increasing concentrations of zinc oxide with a more evident variation for E. coli. These results were confirmed by inhibition halo zones that were larger for complexes of Ag+ZnO against E. coli. As a consequence, the best kinetics of bacterial inhibition was observed for complexes (Ag+ZnO) against E. coli (elimination of organisms after 1 h) indicating the synergism of components and an effective action against Gram-negative species due to the thin peptidoglycan cell wall relative to the Gram-positive species.

Azithromycin reactivity on Ce2(MoO4)3/MWCNT/graphite-based composite electrode: an investigation in electrolytes formulated with CH3OH/H2O blends

HERYKA REGINA ABRANTES DA COSTA[1], Vanessa Erika Abrantes Coutinho[1], André Oliveira Santos[1], Thiago Mielle Brito Ferreira Oliveira[1]

e-mail: heryka.abrantes@aluno.ufca.edu.br

Azithromycin (AZT) is a semi-synthetic antibiotic derived from erythromycin, whose consumption of non-administered doses arouses serious side effects, including the emergence of more resistant bacteria [1]. AZT is also an endocrine disruptor, triggering toxicological effects in non-target organisms. Despite the need to monitor it in relevant samples, assays become limited due to its low solubility (0.1 mg mL-1) in purely aqueous solutions [2]. Little is known about AZT electrochemistry to develop more robust analytical methods, largely due to its structural complexity (15-membered ring with sugar residues attacked) and low interfacial reactivity of the semiconductors employed. In this work, we present data obtained with a composite electrode based on cerium (III) molybdate, multi-walled carbon nanotubes and graphite, here defined as Ce2(MoO4)3/MWCNT/graphite, which showed satisfactory performance to explore AZT oxidation in CH3OH/H2O blends. Semi-emirical simulations indicated that the CH3OH content (5-50%, v/v) alter the blend's dielectric constant, expose hydrogen bonding sites and favor drug solubility. The electrochemical reaction assisted by voltammetry and impedance was already clear on graphite electrode, using phosphate buffer (pH = 8.0; 10% methanol, v/v), but it was amplified and catalyzed by combining MWCNT and Ce2(MoO4)3, respectively, in the sensor composition. The results prospect the Ce2(MoO4)3/MWCNT/graphite composite as a promising material for electroanalytical studies involving AZT in complex matrices.

The search for potential bimodal nanoparticulate probes based on gadolinium (III) chelates and quantum dots has been increasing since the last decade, mainly for its potential as a revolutionary tool in medicine, for magnetic and optical imaging, overcoming the limitations of both techniques [1]. Among the luminescent nanoparticles, we have the class of ternary I-III-VI quantum dots, which are considered environmentally friendly materials, for not having heavy metals as constituents. In addition, they are materials with high absorption coefficient, low thermal conductivity, efficient energy convection and good photostability [2,3]. In this work, we used the hydrophilic ternary quantum dots based on silver, indium and tellurium (AgInTe2) stabilized with MSA. The objective of this study is the conjugation of thiolated DOTA gadolinium (III) complexes modified with different linkers (CYS, PEN and HIS) and ternary quantum dots, obtaining versatile bimodal nanoprobes that provide an optical-paramagnetic improvement and then can be evaluated as potential bimodal contrast agents for optical and magnetic resonance imaging techniques. The synthed nanoplatforms were characterized by ultraviolet and visible (UV-Vis) absorption and emission spectroscopies, relaxometry (20 and 60 MHz, 37ºC).

Thanks to UFPE, CNPq, FACEPE (IBPG), and CESAM/FCT/MCTES (UIDP/50017/2020+UIDB/50017/2020+LA/P/0094/2020) for the financial support.

There is a growing interest in the development of multimodal probesthat have a signal for more than one diagnostic imaging technique. Magnetic resonance imaging (MRI) is a non-invasive technique capable of distinguishing pathological from healthy tissues. However, in some cases, a high local concentration of contrast agents (CAs) is required to improve the observable contrast in images. To overcome this limitation, nanoparticles (NPs) are being associated withCAs, concentratinge several CAs molecules in a single NP, increasing the local concentration of the paramagnetic ion, without increasing the administered dose.[1] These CAs can be associated with NPs that have optical properties, such as quantum dots (QDs).[2] In this work, we intend to associate CdTe QDs with gadolinium complexes, combining the advantages of MRI and optical imaging. The QDs were prepared in water, using glutathione (GSH) as the stabilizer. The DOTA ligand was linked to Cysteamine (CIS), GSH, and L-Cysteine (CYS) and complexed with Gd3+, showing values of relaxivity and stability similar to the DOTA-Gd complex used clinically. TheQDs were conjugated with the thiolated DOTA-Gd complexes, obtaining the bimodal systems. Optical characterization indicated that the QDs remained stable and fluorescent, observing an increase in emission intensity after conjugation. The nanoprobes were characterized by relaxometry at 60 MHz (37 °C) and, 20 MHz (25 °C and 37 °C), obtaining longitudinal relaxivitiesper Gd3+ superiorto the CAs used clinically. Thus, the prepared nanoprobes have the potential to be used asCAs for MRI and optical imaging.

Previous studies carried out by the group revealed that the synergism of simonkolleite (SM) and zinc oxide (ZnO) nanocrystals (NCs) proved to be biocompatible and with antitumor effects. However, the biological effects of SM NCs is still unknown. In order to evaluate the potentiation of the properties of these NCs, nanoconjugation with bioactive compounds is a tool that can be employed. For this purpose, Drosophila melanogaster is a well-established model organism that allows a rapid assessment of the possible effects of nanocrystals as it isa versatile and relatively simple model. Thus, the main objective of this work was to evaluate the biocompatibility of the nanoconjugation of bioactive compounds inSimonkolleite nanocrystals in the fly model. We evaluated the effects of the SM NCs, pureand conjugated with curcumin and quercetin wild type lineage Canton S, in which such substances were mixed in the culture medium at different concentrations. We have evaluated parameters such as pupation per day, total pupation, larval lethality, negativegeotaxis and lifespan of exposed animals. Our data indicates that bioactive compounds conjugated with nanocrystals, when evaluated separately, present biocompatibility. Surprisingly, the well known anti-inflammatory substance quercetin, when combined withNCs, shows toxicity at higher concentrations, possibly due to the exposure of regions of thenanocrystals that were unavailable in the original conformation. Nowadays, we are evaluating the effects of curcumin conjugation on NCs. We hypothe that it may potentiatethe effect of the nanocrystals. Normally, natural substances known for their beneficial effects are expected to improve biocompatibility, however, our results show the importanceof investigating the synergism of the combination of such compounds.

Biocompatibility of Gold doped TiO_2 Nanocrystals in *Drosophila melanogaster*

Auana Raiana da Silva Andrade[1], Jerusa Maria de Oliveira[2], Lucas Anhezini[1], Noelio O. Dantas[3], Anielle Christine Almeida Silva[3]

e-mail: auana.andrade@icbs.ufal.br

Titanium dioxide (TiO_2) can be applied in different fields since they present high thermal stability and catalytic activity, being of great industrial and pharmaceutical interest. The incorporation of gold (Au) in the crystalline structure of TiO_2 nanocrystals can generate new and interesting properties. However, is necessary evaluate the possible side effects and toxicity of the nanocrystals pure and doped in biological systems. Due to their short life cycle, ease of handling and genomic similarity to humans, the ***Drosophila melanogaster in vivo*** model was used to investigate the toxicity induced by orally administered Au doped TiO_2 nanocrystals. The nanocrystals were synthesized and the toxicological test was evaluated on development by inserting L1 larvae (30 larvae/replicate, six replicates per concentration) into different concentrations of Au doped TiO_2 (0.5; 1.0; 2.0; 4.0 mg/ml) added to Drosophila standard medium. The larval and pupal lethality rates were determined, along with the lifespan of animals exposed to the substance. The location of nanocrystals will be observed through fluorescence microscopy to track the tissue localization at different stages of the animal development. Our results suggest biocompatibility at the analyzed concentrations as it did not cause significant increase in larval lethality and decrease in pupation and lifespan. However, further studies are still crucial to evaluate the possible adverse effects of using these nanocrystals.

BIOGENIC IRON NANOPARTICLES USING *Penicillium chrysogenum* AS A STABILIZING AGENT

e-mail: si13silva@gmail.com

Iron nanoparticles obtained from the biogenic synthesis method are non-toxic to humans. They are more biocompatible when compared to their chemically synthesized counterparts, have low toxicity and can help to inhibit the growth of bacteria, fungi and other pathogens. Biogenic Iron (FeNPs) nanoparticles were synthesized using the microorganism ***Penicillium chrysogenum***as a stabilizing agent and Iron III Chloride (FeCl3) as a metal precursor with concentration variations of 1mM and 5mM. After the synthesis, the physical-chemical characterization was performed to obtain the size, polydispersion index (PDI) and zeta potential. Cell viability in the presence of nanoparticles was assessed using the MTT assay, and the comet assay assessed DNA damage in 3T3 cells. A disk diffusion test in agar evaluated the antimicrobial activity. The results showed nanoparticles with a hydrodynamic diameter of 122 ± 1.23 nm, polydispersion of 0.237 ± 0.006 and zeta potential of -16.63 ± 0.45 mV. Viability analysis showed IC50 at 35% concentration, with no indication of genotoxicity. Activity evaluation by disk diffusion and MIC tests showed that NPsFe did not have antimicrobial potential. When evaluating the effects of NPsFe on seed germination, no changes were observed concerning the control. The biogenic synthesis was viable, with NPsFe with favorable characteristics. However, further studies on the cytotoxicity and genotoxicity of NPsFe are needed.

Biomimetic nanoparticles encapsulating paclitaxel for lung cancer therapy

Lorena L. P. Lima[1], Maria Julia Bistaffa[2], Raquel González Sterman[3], Valéria Maria Oliveira Cardoso[4], Valtencir Zucolotto[1]

[1]Nanomedicine and Nanotoxicology Group, Physics Institute of Sao Carlos, University of Sao Paulo, 13566-590, Sao Carlos, SP, Brazil, [2]Instituto de Física de São Carlos - USP, [3]Universidade de São Paulo (*Nanomedicine and Nanotoxicology Group, Physics Institute of Sao Carlos, University of Sao Paulo, 13566-590, Sao Carlos, SP, Brazil*) , [4]Universidade de São Paulo (*Instituto de Física de São Carlos*)

e-mail: Lorenalplima@gmail.com

Chemotherapy is a well-established treatment modality for lung cancer, being paclitaxel (PTX) an FDA-approved drug of choice for non-small cell lung cancer (NSCLC). However, PTX shows severe side effects and high toxicity, besides the potential of resistance development over time [1]. Polymeric nanoparticles offer a promising solution for delivering PTX, due to their unique properties, such as high loading capacity and good biocompatibility [2]. The present study aimed at the synthesis and characterization of a nanosystem based on poly (lactic acid-co-glycolic acid) (PLGA) for carrying PTX, as an alternative for the treatment of NSCLC. The optimization of the synthesis of PTX-loaded PLGA NPs was performed and two different solvents (Dichloromethane (DCM) and Acetone) were tested for the organic phase, as well as two surfactants (Pluronic (PLU) and Polyvinyl Alcohol (PVA)) at different concentrations. The physicochemical characterization of NPs was evaluated using Dynamic Light Scattering (DLS) and Nanoparticle Tracking Analysis (NTA). The PTX-loaded NPs exhibited a diameter of ca. 160 nm ± 36 nm with a PDI of 0.297 and ZP -16.9mV ± 6mV, indicating the NPs electrical stability. NTA revealed an average size of 125.1±1.5 nm, corroborating the DLS measurements. The NPs concentration was 4.47x1012 particles/mL. Scanning electron microscope (SEM) images revealed spherical nanoparticles with diameters in the range of 150 nm. The optimized synthesis conditions allowed the fabrication of PTX-loaded NPs as candidate nanotherapeutics for NSCLC therapy.

e-mail: thifany.caldeira@outlook.com

Lung cancer is one of the most common cancer types worldwide, with high mortality rates.However, conventional therapy for lung carcinoma exhibit some drawbacks includingtoxicity, drug resistance, and serious side effects. Nanoparticles are a promising alternativefor the disease treatment, offering a more precise and less toxic therapy [1]. The nanovesiclesshown here were formed by hybrid cell membranes from lung tumor cells (A549) andlymphoblasts (Jurkat) to encapsulate cisplatin, the gold standard chemotherapeutics for lungcancer. First, both cells were collected, washed with a phosphate buffer (pH 7.4) andthen subjected to a hypotonic solution to swell. After centrifugation, the supernatant wasremoved and the pellet redispersed in a lysis buffer to extract the cell membranes. These cellswere homogenized using animal tissue homogenizer. The membranes were obtained by ultracentrifugation at 100,000 gfor 2 hours at 4°C. The pellet containing the plasma membranes was redispersed in PBS with Complete Protease Inhibitor and kept at -80°C until use. A549 cells and lymphoblastsmembranes were coextruded in a 1:1 ratio, at least 30 cycles, through a 200 nmpolycarbonate membrane to form the hybrid nanovesicle. The nanovesicles containing (mHib_Cis) or not (mHib) cisplatin were characterized by dynamic light scattering (DLS)and nanoparticle tracking analysis (NTA). The mHib nanovesicles exhibited a size of 218 nm,PDI of 0.019, zeta potential of -15 mV and concentration of 5.49 x10^8particles/mL. The sizeof mHib_Cis was 207 nm, PDI of 0.112, zeta potential of -15 mV and concentration of 4.51x10^8particles/mL. The biomimetic nanovesicles produced here may be applied in oncologictherapies improving the quality of patients' life.

With the permanence of the COVID-19 pandemic and its rapid rate of contamination, as well as the high capacity for mutations of the SARS-CoV-2 virus, research is still needed to produce efficient, rapid and low-cost tests. Gold nanoparticles (AuNP) are widely reported in the literature as a material that has low toxicity in biological systems and its biocompatibility makes it a promising alternative in the development of nanoimmunoassays for the detection of SARS-CoV-2. There are already approaches in the literature for applications of nanospherical gold bioconjugates with anti-S. Therefore, this work aims to use surfactant-free Gold Nanostars (GNS) in the development of a biosensor for the diagnosis of SARS-CoV-2. The GNS particles have a spherical center and several tips in its morphology, usually elongated, which can confer a larger surface area, thus making it possible to increase the space for bioconjugation reaction and antibody immobilization. Previous works show that the use of surfactants in the synthesis of these particles impairs the bioconjugation, which could prevent a better performance of the biosensor. CTAB-Free gold nanostars (GNS) were synthesized by the seed-mediated citrate reduction method and characterized by UV-vis spectrophotometry, zeta potential, dynamic light scattering (DLS) and transmission electron microscopy (TEM). This work also aims to study the influence of the morphology of nanostars on the immobilization of antibodies and the interaction with the SARS-CoV-2 Spike antigen, comparing it with the AuNP already reported in the literature.

Glioblastoma (GBM) is a highly malignant form of glioma, with a high risk of recurrence and mortality. Conventional GBM therapy has limited efficacy due to the invasive and heterogeneous nature of the tumor. Currently, the main active molecule used in GBM treatment is temozolomide (TMZ), whose benefits are limited especially due to the resistance mechanisms1. Synthetic chromene-based molecules have proven their potential for cancer treatment, acting on several molecular targets involved in cancer progression2. Here, we investigated cell membrane-coated poly(lactide-co-glycolide) (PLGA) nanoparticles containing novel chromene-based molecules as an innovative anticancer system for GBM treatment. The developed nanostructures coated with the extracted membrane of the U87 human glioblastoma cell line exhibited a diameter of 182 ± 13 nm, and a zeta potential of -10 ± 0.49 mV. Cytotoxicity assays revealed that the cell membrane coated PLGA nanoparticles are more toxic to tumoral cells (U87, U251, and HCB 151) than the uncoated nanoparticles and the free drug, at the same dosage. Additionally, the developed biomimetic system exhibited lower toxicity for non-tumoral cells (HDFn). Our results indicate that the developed nanoparticles may open a new therapeutic opportunity for GBM treatment.

Characterization of liposomes loaded with temozolomide in the aqueous or organic phase

Jessyca Aparecida Paes Dutra[1], Marcela Tavares Luiz[1], Marlus Chorilli[1]

[1]Faculdade de Ciências Farmacêuticas, Campus de Araraquara, UNESP (*Fármacos e Medicamentos*)

e-mail: jessyca.dutra@unesp.br

Glioblastoma multiforme is the most aggressive variant of glioma. Temozolomide (TMZ) is a prodrug that at physiological pH undergoes hydrolysis to form the methyldiazonic cation. The biopharmaceutical properties of the drug limit its delivery to the tumor contributing to treatment ineffectiveness. Encapsulating TMZ in liposomes reduces biopharmaceutical inconveniences and increases efficacy by promoting greater delivery to tumor cells by exploiting the colloidal characteristics of nanosystems and the tumor microenvironment. The DPPC:Chol:DSPE-PEGmal2000 liposomes were produced and TMZ was encapsulated inthe aqueous or organic phase to compare its properties. The characteristics of mean hydrodynamic diameter (nm), polydispersity index (PDI), zeta potential (mV), and encapsulation efficiency (EE) were evaluated. The liposomes presented as a monodisperse population (PDI 0.2) with small size (136.8±0.07; 120.3±0.029 nm) and negative zeta potential (-22.1; -22.5 mV) for the formulations with TMZ in the aqueous and organic phase,respectively. While the encapsulation efficiency of TMZ was 84.37 and 46.65%, respectively.A PDI of less than 0.2 highlights the efficiency of the extrusion method in control. The smallsize promotes delivery to tumor cells, while the negative charge enhances interaction withbiological membranes in their resting state. The colloidal properties do not change according to the incorporation stage of the drug, but there is a difference in EE. These preliminary results demonstrate that TMZ with its amphiphilic character may beincorporated into any phase of the liposomal system without damaging the colloidal properties, however, the difference in encapsulation efficiency should be considered. Sincethe amount of the drug will be essential to obtain the best biological activity with the lowestpossible dose.

Nanotechnology has provided a better therapeutic effect with the nanoparticles- mediated delivery by reducing the toxicity of the drug [1]. Cisplatin is a widely used chemotherapeutic agent that exhibits dose-dependent toxicities in cancer treatment [2]. In this study, we quantify the encapsulated cisplatin in poly(lactic-co-glycolic acid)-based nanoparticles coated with hybrid cell membranes derived from lymphoblast and lung tumor cells (A549)(NP@m) for lung cancer treatment. To this end, we developed and validated a quantificationmethod by ultraviolet-visible spectroscopy for cisplatin derivatized with o-phenylenediamine(OPDA complex; CIS*) at 705 nm following the International Conference on Harmonization(ICH). The nanoparticles were characterized by dynamic light scattering (DLS), nanoparticletracking analysis (NTA), and scanning electron microscopy (MEV). According to the results,this method was selective, accurate (98%), reproducible, and showed repeatability. The limit of quantification is 0,28 µg/ mL of CIS*. The method was also suitable to detect and quantifyCIS* contained in NP@m. The nanoparticles are round with nanometers diameter (142 ±6nm) and negative superficial charge (-6 ±1 mV). The synthesis has 50% of cisplatin encapsulation efficiency and the nanosystems demonstrated effective control of release rates for up to 24 hours. This validation method is sensitive for CIS* quantification, and thenanocarrier shows promise for future in vitro and in vivo experiments.

In the present research we investigate, including negative control experiments with inert gases at the liquid interface, the possibility to induce the CO_2 reduction reaction (CO_2RR) by PLAL of a gold target in water, with the production of carbon monoxide (CO) rich gold nanoparticles (COR-AuNPs). We verify that the CO_2RR controls the biological activity of the produced nanomaterial in endothelial colony forming cells (ECFCs). The biomolecular signaling indicates the ability to behave as carbon monoxide releasing gold nanoparticles, inducing a strong pro-angiogenic activity in endothelial colony forming cells (ECFCs) [1], demonstrated by both *in vitro* and *in vivo* experiments.

Gold nanoparticles (AuNPs) have wide properties and can be used in different areas, including biological applications due to characteristics such as biocompatibility, easy conjugation with biomolecules and unique optical properties. AuNPs applications are most of the time related to their shape and [1]. The use of AuNPs for diagnostic purposes is established by the surface chemistry of AuNPs that can be adapted by incorporating different functional moieties, thus, it is possible to modulate the affinity of AuNPs for a wide range of analytes. Among the main methods for surface functionalization of AuNPs are those based on adsorption, covalent binding and affinity [2]. Gold nanoparticles synthed via magnetron sputtering were functionalized by both methodology based on physical adsorption and covalent binding with anti-SARS-CoV-2 antibodies. The colloidal stability of AuNPs was monitored for their characteristics and the ability of antibody-AuNP bioconjugates to recognize their antigen. To assess the relationship with the capture of specific antibodies, an ECLIA-type immunoenzymatic assay was performed, which proved to be efficient in discriminating negative and positive samples for recombinant anti-SARS-CoV-2 protein. The best strategy for capture was given by adsorption functionalization. The RLU values for 1ug/ml of recombinant protein for functionalization by adsorption reached 2.00 x108 compared to covalent binding with lower RLU of 8.00 x107. Limits of detection using ECLIA for both methods revealed detectable values up to 100ng/ml. The ECLIA technique proved to be efficient for capturing the recombinant SARS-CoV-2 nucleocapsid protein. Future studies will be carried out with clinical samples from the nasopharynx to determine the technique's detection limit.

Tissue engineering is an interdisciplinary field of scientific research that aims to create functional tissues and organs by the synergistic combination between engineering and biological principles. The functionality of the developed tissue is evaluated according to its ability to efficiently perform, equally to or greater, than the original tissue [1]. In addition, it is of great importance that the developed tissue is biocompatible and does not cause any harm to the recipient organism [2]. Therefore, analyzing the cytotoxicity of the developed tissue is essential for the success of the application. The cytotoxicity assay is a primary requirement of all major standards for biological evaluation of developed tissue. The present study aimed to produce non-cytotoxic nanofibers for tissue regeneration. The nanofibers were prepared by electrospinning technique, using polycaprolactone, cellulose nanocrystals, and *Melaleuca alternifolia*essential oil. The cytotoxicity of the electrospun nanofibers to fibroblasts and keratinocytes was evaluated by indirect MTT assay. Additionally, nanofiber samples were characterized by Fourier transform infrared spectroscopy, scanning electron microscopy, and goniometry. The main results indicated that polycaprolactone nanofibers loaded with cellulose nanocrystals and *Melaleuca alternifolia*essential oil were successfully produced and did not present cytotoxicity. Furthermore, the nanofiber samples became more hydrophilic after the addition of cellulose nanocrystals, which points to a good biocompatibility of the developed tissue.

Gold nanoparticles (AuNPs) have been studied in recent decades because they have unique physical, optical and chemical properties such as high surface area, easy conjugation with antibodies and drugs, photothermal characteristics, and its different shapes and s [1]. The search for ecologically sustainable nanostructured materials and their biocompatibility in vitro/in vivo are important characteristics for development and their different applications [2]. Cytotoxicity of gold nanoparticles synthed via magnetron sputtering (MSAuNPs) was analyzed by MTT assay (3-4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) in human fibroblasts (MRC-5) up to a concentration of 50 µg/mL. The preliminary results obtained showed that the nanoparticles presented spherical morphology with varied s. Cell viability tests indicated cytotoxicity in the MRC-5 cell line above a concentration of 35 µg/ml. The production of AuNPs via magnetron sputtering is an eco-sustainable methodology, causing less harm to the environment and more biocompatibility to tissues. Further studies are in focus in order to understand the in vitro mechanisms of action of MSAuNPs with promising applications in the health and environment areas.

Gold nanoparticles (AuNPs) stand out for their advantages such as biocompatibility, adjustable optical properties and easily changeable surface chemistry, being widely used as carriers of drugs and molecules to improve the diagnosis and treatment of diseases (BOTTEON, 2021). This work reports the biocompatibility of gold nanoparticles synthed by green route based on extracts of the Antarctic macroalgae *Palmaria decipiens*(PCAuNPs). The use of biological approaches in the development of ecologically correct processes for the production of PCAuNPs reduces the environmental impact and often reduces the cytotoxicity of these materials against mammalian cells. Antarctic macroalgae produce substances with important biological activities such as antiviral, anti-inflammatory and antimicrobial actions, among others (GIUSTINA et al, 2022). The cytotoxicity of gold nanoparticles biosynthed with the methanolic extract of the Antarctic macroalgae *Palmaria decipiens*was analyzed using the MTT assay in mammalian fibroblasts (L929). Preliminary results obtained showed that PCAuNPs presented spherical morphology with varying between 40 and 60nm. Cell viability tests indicated absence of cytotoxicity in the L929 strain at concentrations up to 100 μg/ml, with an IC50 of 190.27 μg/ml. The characterizationof PCAuNPs synthed by the green route, as well as their antimicrobial and antifungal potential are the next steps of this research to better understand their applicability.

Designing bioactive nanocarriers for the delivery of neurogenic and neuroprotective drugs

Gabriela Colares Ali Ganem[1], Bianca Marçal Pagan[1], João Henrique Lopes[2] [1]Instituto Tecnológico de Aeronáutica (*Departamento de Química*) , [2]Instituto Tecnológico de Aeronáutica (*Departamento de química*)

Mesoporous bioactive glass (MBG) has a unique porous structure that makes it an ideal candidate for use as a drug nanocarrier and delivery system [1]. This is especially interesting for drugs that have low aqueous solubility, fast degradation, low oral bioavailability, and inadequate tissue permeability [1,2]. MBG has excellent solubility in water, good stability, low toxicity, high cellular uptake, remarkable biocompatibility [1,2] and considerable tissue permeability, especially through the blood-brain barrier [2]. The aimof this study is to synthesize mesoporous bioactive glass nanospheres derived from the SiO2-CaO-ZnO-CuO-B2O3 system (in mol%) obtained by the sol-gel method with combined dual functions of bioactivity and controlled drug delivery, and to further investigate their delivery property of neuroprotective drugs as well as the functional effect on neural cellsthrough bioinorganic ion therapy. The morphologies, microstructure, specific surface areasand pore sizes of MBGs were characterized by microscopy, vibrational spectroscopy andnitrogen physisorption, respectively. MBG nanospheres with spherical morphology and internal mesoporous microstructures were successfully prepared by a sol-gel method, exhibiting high specific surface area and mesopore volume. The MBG nanospheres demonstrate excellent bioactivity by inducing apatite mineralization in simulated body fluidsand effective ionic release into this microenvironment. In addition, it to distinct degradability, high charging efficiency and neuroprotective functions. These unique characteristics suggest that the obtained MBG nanospheres may be used for the neural tissue engineering. Cancer is a global public health issue causing numerous deaths. Traditional treatments can cause severe side effects. Nanotechnology offers a promising alternative for cancer treatment, using nanoparticles to deliver drugs directly to the disease site, reducing side effects and improving efficacy. $QPhNO_2$is a naturally-derived molecule with potential anticancer propertie however, its low water solubility hinders clinical development. Nanoencapsulation with PLGA nanoparticles aims to increase solubility, protect the molecule, and improve efficacy.

This study encapsulates $QPhNO_2$in PLGA nanoparticles for anticancer drug use. Stability and drug release kinetics will be investigated. Nanoencapsulation improves solubility of low-water-solubility anticancer molecules.Materials and methods include PLGA, ethyl acetate, Poloxamer 188, and trehalose. A 2^3factorial design optimizes PLGA nanoparticle formulations, analyzing zeta potential, , and PDI. Nanoparticles were prepared using the Emulsification Solvent Diffusion method. Release kinetics, encapsulation efficiency, and in vitro cytotoxicity assays are ongoing. In conclusion, this study develops PLGA nanoparticles containing QPhNO2 for enhanced cancer treatment efficacy and reduced side effects. Further pre-clinical research is needed to evaluate its safety and efficacy as a cancer treatment.

Development and characterization of doxorubicin and quinizarin nanoemulsions for application in Photodynamic Therapy and Chemotherapy of oral squamous cell carcinoma

Ramon Botelho Costa[1], Mariza Aires Fernandes[1], Fernando Lucas Primo[1]

[1]Faculdade de Ciências Farmacêuticas, Campus de Araraquara, UNESP (*Engenharia de Bioprocessos e Biotecnologia*)

e-mail: ramon.costa@unesp.br

Due to their high complexity and resistance, oral squamous cell carcinomas (OSCC) have a difficult therapeutic process and often translate into sequelae or a range of harmful side effects. Thys nanoemulsions (NE) are capable of providing an efficient alternative for the treatment of advanced oral cancer, based in Photodynamic Therapy (PDT) technique and Chemotherapy from delivery of quinizarin (QNZ - photosensitizer) and doxorubicin (DOX - antineoplastic agent), both are responsible to interact with DNA and can modulate several cytotoxic effects through the photodynamic processes induced in tumor cells. NEs system was prepared by the interfacial deposition method with Pluronic F-68 surfactant, soybean phosphatidylcholine, with concentration of 0.05 mg/mL of QNZ in the presence and absence of the DOX at concentration of 1% w/v. For characterization of particle size, polydispersity index and zeta potential were measured by DLS technique. Analysis in absorption and fluorescence emission spectroscopy in 2D/3D mode were performed and used for photophysical characterization as well as to test the quantification and determination of the incorporation efficiency of QNZ and DOX in the formulation. For the unloaded NE and NE/QNZ, NE/DOX and NE/QNZ/DOX, the particle size were 228.1 ± 65.7nm, 200.9 ± 34.5nm, 208.8 ± 46.9nm and 180.8 ± 8.3nm respectively. NEs presented themselves in nanometer scale and monodisperse, with adequate zeta potential between −22mV and −31mV. Through the spectrofluorimetric method developed with a value of $R^2 > 0.99$ we found a high incorporation efficiency of QNZ and DOX in NEs, that was 86% and 95% respectively. Therefore, the nanomaterials were considered promising for synergistic application in antitumor PDT. This work is supported by FAPESP, nº 2022/11326-6 (Grants R.B.C.) and CNPq Universal Project nº 404416/2021-7 (Grants F.L.P).

Development and validation of a method for simultaneous quantification of Erlotinib and Doxorubicin in cell membrane-derived nanovesicles

Raquel González Sterman[1], Valéria Maria Oliveira Cardoso[1], Maria Júlia Bistaffa[1], Valtencir Zucolotto[1]

[1]Universidade de São Paulo (*Nanomedicine and Nanotoxicology Group (GNano), São Carlos Institute of Physics*)

e-mail: raquelsterman@usp.br

The use of cell membrane-derived nanovesicles as drug delivery systems has emerged as a promising strategy to improve the therapeutic efficacy of drugs and as well as to overcome difficulties associated with conventional cancer treatments such as chemoresistance and high toxicity. However, quantifying drug loading efficiency in these systems is crucial for their successful application. Validating the quantification method guarantees the reliability and reproducibility of the data. In the present study we developed a new method for the simultaneous quantification of erlotinib and doxorubicin via high-performance liquid chromatography (HPLC). The method was validated following the International Council for Harmonization (ICH) guidelines, which establishes criteria for accuracy, precision, specificity, and robustness. We applied this validated method to determine the drug loading efficiency of these two drugs in membrane nanovesicles derived from A549 cancer cell lineage. The validation of our method showed that it is linear (erlotinib R2= 0.999; doxorubicin R2 = 0.999), accurate and precise, with a limit of detection (LD) and limit of quantification (LQ) of 0.18 and 0.56 μg/mL for erlotinib, and 0.1 and 0.29 μg/mL for doxorubicin. We also showed the method is specific and robust, and that it can accurately quantify both drugs in the presence of potential interferences. The drug loading efficiency of erlotinib and doxorubicin in the membrane nanovesicles was approximately 50% and 30%, respectively. These results demonstrate the potential of this novel validated method to accurately and simultaneously quantify the drug loading efficiency of erlotinib and doxorubicin in nanovesicles. Moreover, this study contributes to the development of new and safe drug delivery systems for cancer therapy.

Development of a multifunctional magnetic-fluorescent nanomaterial (Fe_3O_4@$mSiO_2$-Cur) and evaluation of its potential for the treatment of topical diseases by photodynamic therapy combined with magnetic hyperthermia

Marla Karolyne dos Santos Horta[1], Bruna Martins de França[1], Lizandra Macedo Nogueira de Castro Alves[1], Evelyn Christyan da Silva Santos[2], Jéssica Dornelas da Silva[3], Cecilia Stahl Vieira[4], Nathália Faria Reis[5], Andréa Regina de Souza Baptista[6], Flavio Garcia[7], Helen Conceição Ferraz[8], Priscilla Vanessa Finotelli[9], Marcel Guimarães Martins[1]

e-mail: marla.horta@hotmail.com

This work aimed to develop a magnetic-fluorescent nanosystem composed by magnetic nanoparticles (MNP) covered by mesoporous silica and containing curcumin as photosensitizer adsorbed on its surface (Fe_3O_4@$mSiO_2$-cur). The purpose of the system is the application in photodynamic therapy combined with magnetic hyperthermia, in order to treat, topically, skin diseases that cause difficult-to-heal wounds, such as the neglected diseases sporotrichosis and leishmaniasis. The use of curcumin in photodynamic therapy is based on its photosensitizing properties, which make it capable of generating reactive oxygen species when activated by light that are harmful to diseased cells, such as cancer cells, and microorganisms, such as fungi, for example. The magnetic nanoparticles were synthed by the coprecipitation method and encapsulated in silica using CTAB as a pore forming agent. The resulting material has an average particle of 12±3 nm, with a silica layer thickness of 3 nm and pore of 4 nm, results obtained by transmission electron microscopy and N_2adsorption isotherm (BET). The adsorption of curcumin on the porous silica matrix was confirmed by EDS and fluorescence optical microscopy. The ILP (Intrinsic loss power) values resulting from the magnetic hyperthermia analysis were 0.63 and 0.35 $nH.m^2.Kg^{-1}$forthe $Fe_3O_4$and Fe_3O_4@$mSiO_2$-cur NPMs, values consistent with the literature and confirmingthe potential treatment by magnetic hyperthermia. In vitro cell internalization assays were performed on sporothrix brasiliensis and Leishmania amazonensis, and a satisfactory internalization profile of the magnetic-fluorescent nanosystem was observed. The results obtained demonstrate that this nanosystem has characteristics suitable for the application of combined treatment of topical diseases, such as sporotrichosis and leishmaniasis, by photodynamic therapy combined with magnetic hyperthermia. Acknowledgements: The authors would like to thank CNPq and FAPERJ.

Development of a nanocomposite based on usnic acidand conjugated polymer for use as bioherbicide

Leandro Oliveira Araujo[1], Montcharles S. Pontes[1], Samuel Leite de Oliveira[1], Anderson Rodrigues Lima Caires[1]

[1]Universidade Federal de Mato Grosso do Sul (*Grupo de Óptica e Fotônica, Instituto de Física,*)

e-mail: leandro.araujo@ufms.br

The growth and demand for food production have been accompanied by an increase in the use of pesticides such as herbicides, insecticides, and fungicides [1]. However, the indiscriminate use of these pesticides has been associated with environmental risks and effects on human health [1]. Therefore, many efforts have been directed towards identifying interactions between contaminants and ecosystem structure to prevent unintentional contamination of these molecules in the environment [2]. In this scenario, the use of nanotechnology presents itself as an alternative to mitigate the risks that these agricultural chemicals cause to the environment. Among the different existing release systems, conjugated polymer nanoparticles (NPCs) emerge as very promising systems [3]. Usnic acid (UA) is a new bioherbicide with potential directed towards the inhibition of photosystem II (PSII), and new formulations derived from nanostructured materials may be a potential improvement for its herbicidal activity. In this study, nanoparticles of the conjugated polymer poly(p-phenylenevinylene) (CNPPV) were loaded with UA to form a new nanocomposite (NPCs-UA) to explore its application as a bioherbicide. The results showed that the nanoformulation had a diameter of 162.1 ± 75 nm, polydispersity of 0.245, and zeta potential of -20.05 ± 4.48 mV. The data also revealed a different release profile of NPCs-AU when compared to free UA. The results showed a slower release for NPCs-UA and an inhibitory effect on the photosystem II of the model plant Brassica juncea.

Development of bevacizumab encapsulated PLGA nanoparticles for lung carcinoma therapy

Maria Vitória Silva Pereira[1], Camila Fernanda Rodero[1], Isabella Luiz Suzuki[1], Valtencir Zucolotto[1]

[1]Instituto de Física de São Carlos - USP

e-mail: mariavitoriasp@usp.br

Lung cancer is a malignant neoplasm of high incidence and mortality, occupying the second place among the most common in the world (International Agency for Research on Cancer - IARC). Although great advances in treatment have been achieved, several drugs still have limitations regarding stability and delivery, making it necessary to search for alternatives to increase their efficiency. This project aims to develop a delivery system based on PLGA nanoparticles for encapsulation and delivery of bevacizumab (BVZ), a antibody that inhibits pro-angiogenic factors in the treatment of lung cancer (NSCLC). PLGA nanoparticles were obtained through the double emulsion method. The PLGA-BVZ were characterized in their hydrodynamic diameter, polydispersity index (PDI) and zeta potential. The sizes were between 171 and 237 nm, PDI between 0.14 and 0.22, the zeta potential between -23 and -27 mV. In addition, 14 days stability tests and Fourier-transform infrared spectroscopy (FTIR) were performed. The results showed that the formulations were stable during the analyzed period. The FTIR results pointed to specific non-covalent interactions occurring between PLGA and BVZ. The results are promising and may contribute to future treatments against lung cancer.

DEVELOPMENT OF LIPID NANOPARTICLES FOR CHEMOTHERAPEUTICS DELIVERY

Mariane Ansoni Ferreira[1], Isabella Luiz Suzuki[2], Camila Fernanda Rodero[3], Valtencir Zucolotto[3]

Solid lipid nanoparticles (SLN) represent a class of important nanocarriers sincethey can encapsulate lipophilic drugs, which can improve their solubility in waterand, consequently, their bioavailability. Photodynamic therapy (PDT) is alsoconsidered a treatment modality for different types of neoplasms. This therapyconsists of the combination of light, photosensitizer (PS), and molecular oxygen(O2), capable of generating oxidative products that can cause cell death.Herein, we developed SLN to encapsulate Paclitaxel (PTX) and the PS 5-aminolevulinic acid (5-ALA) to combine both therapies as an alternative strategyfor lung cancer therapy. The nanoparticles were obtained using a high-energymethod. Compritol ATO 888 was chosen as the lipid matrix, and Poloxamer 188as the surfactant to stabilize the nanoparticle dispersion. Two differentsyntheses were tested, namely SLN_1 and SLN_2, both resulting innanoparticles with average sizes between 169 nm and 170 nm, polydispersityindex (PDI) around 0.3, and negative zeta potential (-26 mV and -28 mV).Stability tests were carried out for 28 days and the results indicated that theformulations remained stable during storage at 4°C, being promising deliverysystems to further studies of lung cancer therapy.

Development of polymeric nanoparticles containing bevacizumab as a new technological platform for targeted drug delivery for the treatment of colorectalcancer

Suzana Gonçalves Carvalho[1], Maria Palmira Daflon Gremião[2], Marlus Chorilli[1]

Colorectal cancer (CRC) is a public health problem; among the types of cancer, it ranks third in incidence and second in mortality [1]. The conventional therapeutic resource for the treatment of cancer is intravenous therapy. However, the lack of selectivity/specificity of antineoplastic agents and their distribution to healthy tissues/organs requires administration in high doses, which can result in toxicity. Among the antineoplastic agents used to treat CRC, bevacizumab (BVZ) stands out as a first-line drug. The encapsulation of BVZ, an angiogenesis-inhibiting antibody, in nanocarriers, has been explored to increase its efficacy in treating colorectal cancer (CRC). The present project aims to develop nanoparticles (NPs) of GG and BVZ by the polyelectrolytic complexation method and modify their surface with chitosan (CS). Different proportions of polymers were tested to obtain the NPs, showing average diameters in the range of 222.6 to 412.1 nm, zeta potential from -16.3 to -40 mV, and PdI from ~222 to 412. Chitosan promoted charge inversion (>+40 mV) in addition to increasing the particle diameter (268 to 400 nm) and the encapsulation efficiency, ranging from 29 % to approximately 60 %. NPs exhibited good physical stability and good mucoadhesive properties by interaction analyses on DLS, NTA, and rheology. The biocompatibility of NPs was evaluated in HCT116, HPMEC cells, human fibroblasts, and macrophages in 2D models and 3D spheroid models, exhibiting dose- and time-dependent cytotoxicity. In addition, the antiangiogenic activity of the nanoparticles was evaluated by the chicken egg chorioallantoic membrane (CAM) model, exhibiting good antiangiogenic properties.

The development of new materials emerges as an alternative to the treatment of cancer, from the combination of nanotechnology and brachytherapy a new area of research was born, Nanobrachytherapy, which through the properties of nanometric materials can achieve better results in the fight against cancer. The objective of this work is classified as radiotherapy, which consists of the use of ionizing radiation to destroy or inhibit the growth of abnormal cells that form a tumor. [1] The ability to integrate NPsAu into biological systems is due to the nanometric dimensions of NPsAu probes which facilitate their incorporation into biological systems, as well as their bioconjugation and non-cytotoxic potential. [2] Taking into account the previous objective, gold was selected as the base element for obtaining nanometric systems, which due to its chemical richness and especially due to the intrinsic properties of one of its radioisotopes, which would allow us in theory to meet the stated objective. . Initially, it was based on the knowledge of the literature, and non-radioactive nanometric systems were obtained, and after a series of stability, characterization and application tests, the radioactive nanometric systems were obtained. Working with radioactive systems posed a great challenge, and up to now it presents us with situations to solve, but we have managed to create a methodology for obtaining, characterizing and applying radioactive gold nanoparticles, and also obtaining positive results from their application.

The unique properties of gold nanoparticles (AuNPs) enable their use in a wide array of applications. The straightforward applicability of AuNPs requires the development of facile synthetic approaches.[1] Commonly employed AuNPs synthesis involve the reduction of gold ions using reducing agents in the presence of stabilizing agents, in a multi-step process. In this context, the use of nitrogen-containing polymers allows for a fast one-pot synthesis of AuNPs where the polymer chains act as both reducing and stabilizing agent.[2] In this work, we used a library of nitrogen-containing polymers to produce polymer-stabilized AuNPs: i) polyethylenimine and derivatives, containing primary to tertiary amino grou ii) poly(aminoethyl)methacrylates, containing only tertiary amino grou and iii) polyoxazolines, containing amide groups. AuNPs synthesis is only feasible at pH >5, thus the protonation degree of the chains is an important parameter. The experimental data suggest hydrodynamic diameters (dH) ranging from 10 to 150 nm. However, since DLS is heavily weighted by particle volume, most of the produced AuNPs are likely to have a dH within 10-30 nm. This is corroborated by UV-vis spectroscopy, where the maximum absorption (λmax) obtained was in 520 to 545 nm range. Surface ζ-potential values in the range -15 to +15 mV were determined, yet the AuNPs were reasonably stable in PB 10 mM pH 7.4, suggesting a synergic electrostatic and steric stabilization. These preliminary findings are expected to potentialize advances towards the practical and ready-to-use manufacturing of polymer-stabilized AuNPs and other metal nanoparticles with applications in a myriad of different fields.

Bradykinin (BK) is a short peptide hormone with a vasodilator effect, belonging to the kininase-kallikrein system, and related to the release of inflammatory mediators. BK has been explored as a blood pressure reducer, and is a well-established active ingredient for antihypertensive drugs in the pharmaceutical industry. However, there are no reports on nanostructured BK materials. Des-Arg9-BK (DBK) is an important BK analog, with a sequence almost identical to that of BK but without an arginine residue. DBK has a different mechanism of action, being a B1 receptor agonist while BK is a B2 agonist. Our objectives were to produce supramolecular structures based on BK and DBK, provide detailed structural data on these assemblies, and investigate whether they exert cellular responses like those of the peptide in its monomeric form. BK and DBK were complexed with DNA fragments. Fluorescence spectroscopy determined the critical aggregation concentrations, while circular dichroism experiments analyzed the secondary structure. Atomic force microscopy and small-angle X-ray scattering investigated the nanoscopic structure of the complexes. Calcium influx analysis in HuVEC cells evaluated the cellular response. We discovered that DNA acts as a template for BK ribbons, leading to the formation of nanoscopic fibrils stabilized by β-sheets. Interestingly, this effect is not observed for DBK. Furthermore, BK preferentially binds to the major grooves of DNA duplexes, while DBK intercalates between nucleotide bases. Importantly, BK-DNA fibrils were found to modulate calcium influx in HuVEC cells, thus preserving the bioactivity of the native peptide. We demonstrate a feasible strategy to fabricate BK-based nanostructured matrices that are potentially exploitable for the development of biomaterials endowed with hypotensive capabilities. for the development of biomaterials endowed with hypotensive capabilities.

Effects of Bisphenol-A in giant unilamellar vesicles as mimetic models of a tumoral cell membrane.

Vitória Barossi[1], Mateus Dassie Maximino[1], Priscila Alessio[1] [1]Universidade Estadual Paulista Júlio de Mesquita Filho - Faculdade de Ciências e Tecnologia - Campus de Presidente Prudente (*Física*)

e-mail: vitoriabarossii@gmail.com

One of the greatest challenges facing humanity relates to the availability and quality of water. Every day several chemical compounds are dumped directly or indirectly into nature and end up entering human and animal consumption. One of the most worrying classes is the emerging pollutants that cause interference in the endocrine system. One is Bisphenol A (BPA) [1], a compound used in manufacturing plastics, present in packaging and resins, and released by hydrolysis. Another concern is about the effects of this compound on tumoral cells. Thus, this work aims to study the effects of the pollutants on tumoral cell membrane models from the creation of giant unilamellar vesicles (GUVs) [2], which mimic biological membranes. The lipids used in the construction of GUVs were DOPC and DPPS, together, ata ratio of 80/20, or separately, to analyze the effects of BPA at a concentration of 1x10-4 mol/L. Through phase contrast microscopy, it was observed that after contact with the pollutant, the vesicles became unstable, losing their spherical shape, and increased in ; adjacent formations appeared inside (endocytosis of the external environment) and outside (buddings). In conclusion, the presence of Bisphenol A in the external environment induced diverse effects in the bilayers of DOPC and DPPS, and additional studies must be carried out to unravel the specific molecular interaction responsible for the effects.

Encapsulation of antimicrobials in lipid corenanocapsules

Janaína Artem Ataide[1], Vitória Eduarda Fassini[1], Luiza Aparecida Luna Silvério[1], Érica Mendes dos Santos[1], Priscila Gava Mazzola[1]

[1]Universidade Estadual de Campinas (*Faculdade de Ciências Farmacêuticas*)

e-mail: janaina.a.ataide@gmail.com

Substantial advances happened in the development of functional nanomaterials towards biomedical materials, mainly for targeted therapies and drug delivery. Lipid core nanocapsules (LCN), a class of nanocapsules in which a polymeric shell is arranged around an inner core and is formed by a dispersion of a liquid lipid and a solid lipid, have gained attention since they can vehicle actives soluble in their lipidic core or polymeric shell [1]. Our objective was to encapsulate fluconazole and rifamycin SV in LCN, aiming to improve existing treatments for fungal and bacterial infections by controlling their release. Empty-LCN (unloaded), Flu-LCN (LCN loaded with fluconazole) and Rif-LCN (LCN loaded with rifamycin SV) were produced with mean diameter around between 220 and 230 nm, PDI of 0.13 to 0.15, and ζ-potential of -27mV. Fluconazole presented a type II distribution in LCN, with encapsulation efficiency of 8.0%. On the other hand, rifamycin SV presented a type III distribution, with encapsulation efficiency of 66.2%. Around 53% of fluconazole was released in the first 7h, reaching 77% in 48h; while less than 5% of rifamycin SV was released in the first 8h, reaching 21% in 48h. Empty-LCN did not show any in vitro antimicrobial activity, while loaded-LCN showed similar MIC to free antimicrobials when tested S. aureus, P. aeruginosa and C. albicans microorganisms [2]. Thus, LCN can be considered a promising drug delivery system for antimicrobials, which could be further evaluated for topical applications.

e-mail: jessica.santos@ufrn.br

Jambolan (*Syzygium cumini*L.) has been studied as a source of antioxidants and food colorant due to its phenolic composition, which includes anthocyanins [1]. This study aimed to encapsulate an extract rich in anthocyanins (ANT) and other phenolic compounds (PC) from jambolan obtained by ultrasound-assisted extraction [2]. For encapsulation, two formulations [2.2 g extract (20 mg ANT; 97 mg PC), 0.5 g pectin, 1.5 g whey protein concentrate (C) or isolate (I)], were precipitated in two antisolvent phase compositions: absolute acetone (C100, I100) or 50% v/v (C50, I50). The particles were characterized by PC and ANT encapsulation efficiency (EE%), particle by DLS, Zeta potential, FTIR, and X-ray diffraction. The results for EE% of ANT [C100: 56.89% (1.29); C50: 48.65% (1.74); I100: 35.24% (1.24); I50: 36.33% (2.76)] differed ($p < 0.05$) between formulations, however, EE% of PC [C100: 82.39% (1.59); C50: 73.81% (6.72); I100: 84.61% (1.64); I50: 75.80% (6.91)] did not differ ($p > 0.05$). Zeta potential at pH 4.7 varied from −8.3 to −10.3 mV. Particle s of WPI-based formulations [I100: 661.3 nm (79.2); I50: 302 nm (27.6)] were smaller than WPC-based formulations [C100: 1263.8 nm (124.7); C50: 1156 nm (60.4)]. FTIR showed that all encapsulated presented similar spectra to those of the proteins used, in addition to displacements and formation of new bands (1072 to 1022 cm^{-1}in C100, C50, and I50 and in 1072 and 1026 cm^{-1}in I100). The diffractograms showed that all encapsulated presented an amorphous structure. These results show the potential of nanoprecipitation and the combination of encapsulating agents in producing particles containing jambolan phenolic-rich extract, which can protect and optimize the application of these compounds.

The emergence of super-resistant bacteria in livestock is a worldwide problem. Silver nanoparticles (AgNPs) have received significant attention in recent years due to their potential use as antibacterial agents. Once synthesized, AgNPs can interact with biomolecules, including proteins, which can lead to the formation of a protein corona around the particle. Endolysins from bacteriophages have also been highlighted as biomaterials for therapeutic applications. Endolysin PlyB221 has a modular structure composed of enzymatically active domains (EADs); and a cell wall binding domain (CWBD) that recognizes and brings endolysin to cell wall associated ligand molecules with high specificity. In this study, AgNPs was synthesized using a chemical reduction method and characterized using various techniques, including transmission electron microscopy, dynamic light scattering and UV-Vis spectroscopy. The production of the recombinant endolysin PlyB221 was evaluated in SDS-PAGE, and the interaction of AgNPs with PlyB221was evaluated by monitoring the size, zeta potential, and the absorption band in the UV-Vis. Our results showed that AgNPs were successfully synthesized with a mean diameter of 7 nmand a zeta potential of -30 mV, and the PlyB221 with a mean diameter of 144 nm and a zetapotential of -13,5mV. The interaction of AgNPs with endolysin showed a significant increasein size for 2300nm and variation of the zeta potential for -8mV. Through UV-Vis it was possible to verify a shift in the silver absorption band (396 nm to 420nm), whichdemonstrates the interaction with endolysin, leading to the formation of a corona protein. These findings have implications for the development of theranostic platforms for use in agriculture.

Establishment of an in vivo platform to evaluate theeffects of zinc nanocomposites and nanoconjugates with curcumin in an Alzheimer's model

e-mail: lucas.anhezini@icbs.ufal.br

Alzheimer''s disease (AD) is a fatal neurodegenerative pathology, for which there is no cure. This scenario is intensified by exposure to nanoparticles due to their neurodegenerative effects. Curcumin, a bioactive compound, in addition to present neuroprotective effects, can be used as a biomarker of AD. As some pharmacokinetic properties of this bioactive interfere with its therapeutic effects, the nanoformulation is a tool that can be used as a drug delivery system. Drosophila melanogaster is a well-established model organism that allows the creation of mutant AD-related phenotypes and enables a rapid assessment of the possible effects of nanomaterials. Therefore, our main objective was to establish an in vivo platform to evaluate the effects of nanocomposites and nanoconjugated curcumin in the AD model. Through the UAS-GAL4 system and lineages of flies carrying human mutations in the amyloid precursor protein (APP), we performed the expression of the mutant protein in the central nervous system during development, leading to neurological and motor damage anda decrease in life expectancy. We evaluated the effects of the nanomaterial Simonkolleite,pure and conjugated with curcumin, in our AD model analyzing life expectancy, motor behavior and toxicity in the eyes of affected animals. Our experiments culminated in the establishment of a model in which expression of the APP carrying a human mutation leads to severe neurodegeneration, premature death and cellular toxicity in the animals eyes. Together, we were able to develop a platform for screening biomolecules conjugated to nanomaterials that may contribute to the development of new therapies for AD. We are currently testing whether Simonkolleite conjugated to curcumin can play a neuroprotective role in our in vivo Alzheimer model, reducing the damage caused by exposure of the central nervous system to nanomaterials throughout life and in the establishment of neurodegenerative diseases.

Establishment of an *in vivo* platform to evaluate the effects of nanocomposites and nanoconjugated Curcumin in a C9orf72 Amyotrophic lateral sclerosismodel.

Renata Barbosa Campelo[1], Larissa Iolanda Moreira de Almeida[2], Jerusa M. de Oliveira[3], Ivis de Melo Agra[2], Anielle Christine Almeida Silva[2], Lucas Anhezini[1]

e-mail: renata.campelo@icbs.ufal.br

Amyotrophic lateral sclerosis (ALS) is a fatal and incurable disease characterized by progressive degeneration of motor neurons. This scenario is intensified by the exposure to nanoparticles due to their neurodegenerative effects. Studies demonstrate the effectiveness of Curcumin, a bioactive compound, in neurodegenerative disorders, however, the effects of this natural compound in ALS have not yet been fully elucidated, since some pharmacokinetic properties affect its therapeutic effects. To overcome such limitations, nanoformulation is a tool that can be employed. *Drosophila melanogaster* is a well-established model organism that allows creating mutant phenotypes related to ALS and enables quick evaluation of the possible effects of nanomaterials since it is an economical and dynamic model. Our main goal was to establish an *in vivo* platform to evaluate the effects of nanocomposites and nanoconjugated Curcumin on an ALS model. In order to express the C9orf72 ALS transgene containing 30 hexanucleotide (G4C2) repeats, we used the UAS-GAL4 system with drivers that control the gene expression on the eyes and motor neurons of the animals. The animals completed their development at 29°C to increase the transgene expression. We evaluated the effects of the nanomaterial Simonkolleite, pure and conjugated with Curcumin, on our ALS model based on lifespan, larval and adult motility, and eye cell toxicity in affected animals. Transgene expression caused severe eye toxicity compared to control, while its expression in motor neurons led to severe degeneration, causing a decrease in lifespan. We are evaluating the neurodegenerative potential of the nanocomposite. Therefore, we were able to establish a model that mimics the phenotypic characteristics of ALS patients. Our hypothesis is that Curcumin performs a neuroprotective role in our *in vivo* model, reducing the damage caused by nanomaterials.

Evaluation of antitumor effect of PEGylated nickel ferrite nanoparticle-mediated magnetohyperthermia

Despite extensive advances in the field of radiotherapy, chemotherapy and surgery, improving survival and quality of life for cancer patients has still been a challenge. For this reason, investigations combining conventional therapies with other modulators are performed [1,2]. In this work, we investigated the effect of magnetohyperthermia (MHT) induced by PEGylated nickel ferrite (PEG-NiF) nanoparticles on breast cancer (MCF-7) cells. The nanoparticles (NPs) were synthetized by hydrothermal method and characterized by X-ray diffractometry, dynamic and electrophoretic light scattering, thermal analysis, infrared spectroscopy, Mössbauer spectroscopy and vibrating sample magnetometry. PEG-NiF NPs heating profile using AC magnetic field of 300 A, with 279 kHz of frequency, was studied at different concentrations (100, 200 and 350 $\mu g.mL^{-1}$) and correlated with their potential cytotoxic effect against MCF-7 cells. The results evidenced the formation of spinel phase with crystallite size of 25.6 ± 0.5 nm, hydrodynamic size below 150 nm, saturation magnetization of 53 $emu.g^{-1}$ and superparamagnetic behavior at room temperature. The heating response was tuned by PEG-NiF NPs concentration reaching 42 ºC at 350 $\mu g.mL^{-1}$. Cell viability remained unaffected by the application of the AC magnetic field alone. On theother hand, when it is combined with increasing concentrations of PEG-NiF NPs the inducedMHT was harmful to MCF-7 cells resulting in up to 83 % of cell death. This antitumor effectagainst MCF-7 cells was 22 % greater than that of PEG-NiF NPs alone. Based on theseresults, we could envision the application of the PEG-NiF NPs as a magnetohyperthermiaagent.

e-mail: maria.duarte@icf.ufal.br

The nanofibers were obtained by a solution of silver nanoparticles (NPAg-P) with red propolis from Alagoas (RPA) incorporated into the polymer matrix of polycaprolactone (PCL). The electrospun nanocomposites were named PCL-E, E1%, E2% and E5%. The characterization of the material was performed by: X-Ray Diffraction (PXRD), thermogravimetry (TG), Differential Exploratory Calorimetry (DSC), Scanning Electron Microscopy (SEM), mechanical test, release and antimicrobial activity. Metallic silver crystalline planes visualized by PXRD confirm the obtainment of NPAg-P. By TG, it was possible to observe that the decomposition of the products compared to the pure polymer did not change, but the DSC curves decreased in the melting temperature because of the reduction of the crystallinity of the compounds due to the increase of NPAg-P. The morphology of the nanofibers was evaluated by MEV and it was observed that at E5% there was a decrease in the fiber and greater uniformity of distribution, when compared to the other concentrations. In the mechanical test, it was observed that the addition of silver resulted in a decrease in the elasticity and resistance of the material, compared to pure PCL fiber. For the release test, there was a release of 0.0833 µg/mL in 24h. In the antimicrobial activity, inhibition halos (8.0 mm) were observed for the evaluated bacteria with the E5% nanofibers. For isolated E5%, inhibition halos of, on average, 8.0 mm were observed. For RPA, a halo of 6.5 mm was observed. It was observed that NPAg-RPA nanofibers are a promising antimicrobial agent, without toxicity and with proven synergism between the properties of the material and silver. The results of the characterization analyzes demonstrate a potential material for application as a dressing.

Exploring Nucleotide-based Metal-Organic Frameworks for Quantum Dot Intracellular Delivery

Renata Lara Mori[1], Lucas Rodrigues de Mello[1], Italo Marcos Nunes de Oliveira[2], Emerson Rodrigo da Silva[1]

[1]Universidade Federal de São Paulo (*Biofísica*) , [2]Universidade Federal de Alagoas (*Física*)

e-mail: renata.mori@unifesp.br

Nucleotides are effective ligands that can coordinate with metal ions, particularly transition metals, leading to the formation of metal-organic frameworks (MOFs). These nanoscopic aggregates have diverse biomedical applications, including intracellular drug transport, therapeutic molecule distribution, and bio-imaging. Quantum dots (QDs) are semiconductor nanoparticles with unique optical properties, making them suitable for combination with biocompatible nanostructures in biomedical applications. This study aimed to synthesize supramolecular complexes comprising guanosine-based nucleotides, metal ions, and graphene quantum dots, followed by detailed structural characterization and in vitro testing against tumour cell lines. A protocol was established for solubilizing guanosine monophosphate (GMP) in the presence of metal ions, such as Zn, Mg, Mn, Fe, Co, Cu, and Ni, along with graphene quantum dots. The nanoparticles results were analyzed using atomic force microscopy, scanning electron microscopy with energy dispersive spectroscopy (EDS) and steady-state fluorimetry. The complexes were also tested for cytotoxicity against HeLa cells, with successful production of ordered and crystalline GMP/QD nanoparticles observed in the presence of the aforementioned metals. Notably, MOFs prepared with Fe3+ were found to modulate the fluorescence capabilities of graphene QDs, leading to shifts in absorption/emission maxima or changes in fluorescence yield. The MOFs exhibited excellent tolerance by cells up to concentrations of mg/ml. Overall, this study presents a facile protocol for the development of nucleotide-based nanoparticles incorporating QDs, with promising applications in the development of biomaterials.

Exploring the Hydrogelation Behavior of a Designed Decapeptide for Cell Morphogenesis

Lucas Rodrigues de Mello[1], Emerson Rodrigo da Silva[1]

[1]Universidade Federal de São Paulo (*Biofísica*)

e-mail: lucasr.mello@hotmail.com

For this work designed nanostructured hydrogels using the sequence DGRL4DGW, a selfassembling peptide containing motifs from osteopontin (DGR) and fibronectin (DGW), two significant proteins involved in osteogenesis and cell adhesion. The resulting hydrogel was characterized using cutting edge biophysical techniques such as small angle neutron scattering under controlled temperature and atomic force microscopy. Furthermore, we explore the use of these matrices in promoting the growth of living cells and modulating the formation of three-dimensional cell spheroids by confocal microscopy and monitoring the viability of those cells along the time. The DGRL4DGW hydrogel was possible to be made by quick-gelation methods with small amounts of peptide (99% water and 1% of peptide), was thermostable and also maintained NIH3T3 and HeLa cells for 3 days in cell culture[1].

Gallium and niobium containing drug-loadable mesoporous bioactive glass nanoparticles

Luis Oliveira[1], João Henrique Lopes[1]

[1]Instituto Tecnológico de Aeronáutica (*Química*)

e-mail: lfmo2000@gmail.com

Traditional osteosarcoma therapies tend to focus solely on eradicating residual cancer cells and often fail to promote local bone regeneration and even inhibit it due to lack of precise control over target cells, i.e., the treatment affects both normal and cancer cells [1,2]. An alternative for these problems is the use of bioceramics such as bioactive glasses (BGs) for targeted ionic therapy, through the release of ions that enhance osteogenic response and control micrometastasis [1]. In this work, we report the synthesis and characterization of sol-gel bioactive glasses containing niobium (Nb) and gallium (Ga), a multifunctional glass that has potentiating effects for bone repair and regeneration, concomitantly with a bone cancer targeted therapy. The synthesis is carried out via the sol-gel route coupled to self-propagating combustion method, developed by our research group [1]. The Ga3+ into the vitreous network promotes an increase in the network connectivity, contributing to an increase in the degree of polymerization of the glass, since part of the calcium ions that behave as network modifying agents were replaced by gallium ions that act as network formers. SEM microscopy for glass samples revealed a morphology and porosity structure characteristic of mesoporous bioactive glass (MBG) and also indicated the samples were meso-porous and formed by the stacking of nanometric plates, generating material with a high surface area and high porosity. These features are critical factors for the control of glass reactivity and bioactivity, which are very important for biomedical applications. Acknowledgments:The authors are grateful for the financial support provided by the São Paulo Research Foundation (FAPESP, 2022/03247-6). This research was carriedout at the Laboratory of Biomaterials and Biointerfaces (BBLab) of the ITA.References:[1] Medeiros, G. S et al. JNCS, 599, 121962 (2023). [2] Souza, L. Carbon dots are a novel promising class of nanomaterials that have aroused growing attention due to their unique photoluminescence (PL) properties. These recently synthesized zero-dimensional nanomaterials can replace traditional semiconductor quantum dots, which exhibit significant toxicity and higher costs. However, most of the described carbon dots possess blue light emission under UV light, which is not suitable for cellular imaging and biological medium. Therefore, CDs with long-wavelength emission by nearly visible light sensitization attract enhanced attention. But successful fabrication of functional carbon dots is only half the battle. The application of CDs in modern technologies requires very small quantities of ultrapure CDs with precisely controllable size, shape, composition, and surface features. Recently, scientists have given more attention to the fact of the formation of molecular fluorophore species as by-products during CD synthesis. The presence of molecular fluorophores in the final sample leads to mistaken conclusions regarding the fundamental properties of these emerging nanoparticle thus, fluorophores are known to give rise to excitation-independent PL behavior. Therefore, a successful, efficient, affordable, and fast purification process before is needed to obtain reliable results on the properties of CDs. Essner et al. studied over 550 research articles and revealed that more than half of them used insufficient purification processes. Thus, the evaluation of the purification process of CDs is needed. In this study, we synthesized green-emitting phosphorus-nitrogen doped carbon dots via hydrothermal method from citric acid, ethylenediamine, and phosphonic or phosphoric acid as precursors. The reaction products were purified by two of the most traditional and commonly used methods - dialysis and preparative column chromatography. The performance of each method was evaluated and compared.

Green study of ZnO nanoparticles as photosensitizers in Photodynamic Therapy

Hulder Henrique Zaparoli[1], Daniela Gomes Bornal[1], Marcela de Oliveira[1], Paulo Noronha Lisboa-Filho[1], Marina Piacenti da Silva[1]

[1]Universidade Estadual Paulista (*Física e Meteorologia*)

e-mail: hulder.zaparoli@unesp.br

Photodynamic therapy (PDT) is a relatively new modality of disease treatment that has aroused interest in tumor therapy research. PDT involves the combination of three basic factors light sources, oxygen, and a photosensitizer (PS) [1]. PS requires being non-toxic to normal tissue in the dark and causing photodamage with an appropriate light source [1]. Studies show that the use of nanoparticles can increase the efficacy of PS in PDT, and zinc oxide nanoparticles (ZnO-NPs) are considered promising due to their unique properties. This study aimed at the green synthesis of ZnO-NPs for application as PS in PDT. The green synthesis process was carried out by microwave-assisted hydrothermal route using soybean extract as a reducing agent [2]. The ZnO-NPs were characterized by scanning electron microscopy, Fourier-transform infrared spectroscopy and X-ray diffraction, and used as a catalyst in the photodegradation assays of methylene blue dye, under black light. Photodegradation assays were carried out to test the effectiveness of the synthesized nanoparticles as photosensitizers. The XRD spectrum showed crystalline structures corresponding to ZnO, the FTIR showed the chemical absorption bands, and the morphology of the nanoparticles was confirmed by SEM. Thus, the preliminary results indicated the formation of ZnO-NPs and promising conditions for the application of these nanoparticles as photosensitizers for use in PDT.

Green synthesis of zinc oxide nanoparticles (ZnO NPs) involves the use of eco-friendly, non-toxic, and renewable sources, which has gained significant attention in recent years due to its potential applications in various fields. Some of the commonly used green synthesis methods for ZnO NPs include plants, microorganisms, and natural polymers. Tea tree essential oil is an aromatic oil that is derived from the leaves of the tea tree. Tea tree essential oil has been reported to have potential as a chelating agent and/or an oxidizing/reducing agent in the biosynthesis of NPs. In this study, ZnO NPs were synthesized using 0,15 M aqueous solution of zinc nitrate hexahydrate as a precursor, and 40g/L aqueous emulsion of tea tree essential oil containing Tween 80. The tea tree essential oil was added dropwise to the precursor solution, followed by the addition of a sodium hydroxide solution to adjust the pH to 8. The mixture was then stirred for four hours at 60°C, leading to the formation of ZnO NPs. The tea tree essential oil was found to be an effective reducing agent for the synthesis of zinc oxide nanoparticles, and the characterization carried out using Scanning Electron Microscopy (SEM) reveals the presence of zinc oxide nanoparticles in its agglomerated form resulting nanoparticles had a size range of 60-100nm. The average crystallite sizes of ZnO NPs calculated via X-rays diffraction analysis are found to be 25 nm. A UV-Vis absorption peak was observed at 380 nm, which is specific for ZnO NPs. FT-IR spectroscopic analysis shows absorption peak of Zn-O bonding between 442 and 512 cm-1. Overall, the use of tea tree essential oil in the synthesis of ZnO NPs is a promising approach that offers several advantages, such as eco-friendliness, low cost, and scalability. However, further research is needed to optimize the synthesis process and to evaluate the potential applications of these nanoparticles in various fields.

Green synthesis of gold nanoparticles with red propolis extract and its cytotoxic potential in mammalian fibroblasts

Marina Della Giustina[1], Jordana Bortoluz[2], Francine Girardello[1], Janaina da Silva Crespo[2], Marcelo Giovanela[2], Mariana Roesch Ely[1]

The application of metallic nanoparticles has been explored in recent years due to their biocompatibility, adjustable optical properties and easily changeable surface chemistry. Studies with gold nanoparticles (AuNPs) have reported their functionality as drug carriers and molecules to improve diagnosis and treatment of diseases (BOTTEON, 2021). This work reports the green synthesis of gold nanoparticles with red propolis extract and its cytotoxic potential in mammalian fibroblasts (PVAuNPs). The development of ecologically correct processes has been increasing to optimize the production of PVAuNPs, using green technologies and contributing to the reduction of the environmental impact. This approach has been studied to replace methods commonly used in industry and thus reduce the cytotoxicity of these materials against cell lines (BANDEIRA, 2020). Propolis is a resinous product produced by bees, the variety of red propolis is obtained exclusively in northeastern Brazil and presented several biological activities such as antibacterial, anti-inflammatory, antioxidant, antitumor, among others (FROZZA, 2013). The cytotoxicity of gold nanoparticles biosynthed with red propolis ethanol extract was analyzed using the MTT assay in mammalian fibroblasts (L929). The preliminary results obtained showed that the nanoparticles had a spherical morphology with a varying between 40 and 60nm. Cell viability tests indicated absence of cytotoxicity in the L929 strain at concentrations up to 50 μg/ml, with an IC50 of 207.23 μg/ml. More studies are needed to determine the chemical and physical characterization of these biosynthed AuNPs, as well as to evaluate their antimicrobial and antifungal potential to better understand their applicability.

Gum arabic-gold nanorods composite effects on macrophages: towards tumor microenvironmentevaluation

Jacqueline Gonçalves dos Santos[1], Anderson Fraga da Cruz[1], João Luiz Aldinucci Buzzo[1], Stellee Marcela Petris Biscaia[1], Yasmin Carla Ribeiro[1], Ábner Magalhães Nunes[2], Mario Roberto Meneghetti[2], Edvaldo da Silva Trindade[1], Fernanda Fogagnoli Simas[3], Carolina Camargo de Oliveira[1]

e-mail: jacqueline.santos@ufpr.br

Macrophages are immune cells that play an important role in tumor microenvironment (TME). Gum Arabic (GA) is a well-known non-cytotoxic biopolymer that present immune modulation properties, and that has been used for nanoparticles synthesis and stabilization. In a previous work we have demonstrated in vitro gum arabic-gold nanords (GA-AuNRs) composite biocompatibility to fibroblasts, and their ability to reduce melanoma malignant characteristics. In vivo, GA-AuNRs impaired melanoma primary tumor growth in mice [1]. Now we investigate GA-AuNRs ability to activate macrophages towards TME modulation and melanoma progression impairment. The macrophage cell line RAW 264.7 was used to determine GA-AuNRs (from 1.8 ng/L to 18 mg/L) effects after 96 h, on cell viability (neutral red uptake), density (crystal violet), and nitric oxide (NO) production (Griess). GA was used as control and 3 independent experiments were performed. No statistically significant changes in cells viability and density were observed up to 0.18 mg/mL. NO production was not altered in the presence of non-cytotoxic GA-AuNRs concentrations. Primary macrophages from C57/BL6 mice bearing or not melanoma were used to determine GA-AuNRs anti-tumorigenic phenotype (M1) induction. All procedures using animals were approved by the Ethical Committee (SCB-UFPR CEUA № 1485). M1 phenotype was investigated by cells immunophenotyping, cytokines production (CBA kit), reactive oxygen species (ROS - DCF-DA assay), and phagocytosis activity in a preliminary study. The results suggest that M1 macrophage phenotype might be induced by GA-AuNRs, but further experiments need to be performed to validate it. In conclusion, in vivo TME modulation by GA-AuNRs composite could be occurring together with melanoma cells malignancy decrease. e-mail: italo@fis.ufal.br

Over the past decade, several studies have investigated the viability of using carbon dots as photosensitizers in antimicrobial photodynamic therapy. The primary motivation is the substantial increase in the number of pathogenic strains resistant to antibiotics and disinfectants, which has caused an enhancement in mortality rates and health care costs. Therefore, many efforts have been made to develop new strategies to inactive deadly pathogens and to improve sterilization procedures. A remarkable attention has been devoted to photodynamic therapy with carbon dots as the photosensitizers. Like molecular photosensitizers, carbon dots may generate reactive oxygen species (ROS) upon photoexcitation in a specific wavelength. The main goal is the study of nanoparticles exhibiting an efficient intersystem crossing between singlet and triplet excited states, which may favor ROS generation through energy transfer to oxygen molecules dispersed in the carrier medium. Although several methods and precursors have been used, most carbon dots exhibit a low efficiency in ROS generation upon photoexcitation. In this context, the present study is devoted to investigate the physicochemical properties of carbon quantum dots (CD-MR) obtained from hydrothermal synthesis using methyl red as the precursor. CD-MR's time-resolved and steady-state fluorescence is investigated, considering the thermal effects on the photoluminescence. The possibility of using CD-MR to photogenerate reactive oxygen species (ROS) is also analyzed, where a high singlet oxygen quantum efficiency is verified. Moreover, it is studied the antimicrobial activity of carbon dots against bacteria (S. aureus and E. coli) and fungi (C. albicans and C. neoformans) strains upon photoexcitation at 532 nm. Using the susceptibility test of Kirby-Bauer, also labeled as the disk diffusion test, it is observed that such carbon nanoparticles present antimicrobial activity against gram-positive bacteria and fungi strains.

Hydrocolloid biobandage is produced from green synthesis using natural biopolymer and green propolisfor treatment of dermal lesions

The concern for sustainability has driven medical research to search for alternatives to synthetic materials[1]. Developing effective biodegradable dressings that can treat skin lesions non-invasively and generate less waste is highly desirable. This work describes the green production of a biofilm-based on chitosan and albumin and its application as a carrier vehicle for the controlled release of propolis extract, for use as a hydrocolloid biobandage in the treatment of dermal lesions. In this study, a multifactorial optimization approach, involving core composite design and full-factor design (2 3), was used to evaluate the main factors that influence biofilm formation and optimal synthesis conditions. The factors evaluated were (i) mass of chitosan and albumin (0.5-2g), (ii) concentration of acetic acid (1-5%, w/v), and (iii) the presence or absence of a cross-linking agent (glutaraldehyde, 0-0.5%). As a result of this optimization, it was observed that using (i) a mass of chitosan (1.5g); (ii) the concentration of acetic acid (2.0%, m/v); and (iii) the absence of glutaraldehyde allowed to produce a resistant biofilm with a high degree of tumescence, enabling a high load capacity of the drug. The biofilm generated under optimal conditions was characterized using specific characterization techniques (SEM, FT-IR, DRX, and TGA). In vitro studies to assess (i) drug loading capacity, (ii) controlled drug release, (iii) membrane permeation, and (iv) toxicity are ongoing and will be presented at the event.

Impedimetric biosensor for tuberculosis diagnosis

Luisa Vogado Ribeiro[1], Valtencir Zucolotto[1], Juliana Cancino-Bernardi[2]

[1]Nanomedicine and Nanotoxicology Group, Physics Institute of Sao Carlos, University of Sao Paulo, 13566-590, Sao Carlos, SP, Brazil, [2]Universidade de São Paulo (*Laboratory in Bioanalytical of Nanosystems (LBioNano), Chemistry Department, Faculty of Philosophy, Sciences and Letters of Ribeirão Preto*)

e-mail: luisa.vogado@gmail.com

Tuberculosis (TB) is a mycobacterial infection commonly caused by the etiologic agent Mycobacterium tuberculosis. Reported over a century ago, TB was the leading cause of death from a single infectious agent until the coronavirus (COVID-19) pandemic, ranking above HIV/AIDS [1]. The traditional methods for TB diagnosis, i.e. sputum smear microscopy, liquid culture, and recently, molecular tests, present many limitations, such as the low sensitivity and long periods of time to obtain the results, frequently leading to incorrect diagnosis and unnecessary treatment [2]. Electrochemical sensors have attracted attention due to their simplicity, low-cost instrumentation, very low detection limits, and rapid response [3]. In this study we present an electrochemical impedimetric immunosensor for the detection of recombinant protein CFP10:ESAT6 forthe diagnosis of M. tuberculosis. The immunosensor was developed onto indium tin oxide (ITO) electrodes modified by 3-aminopropyltrimethoxysilane (APTES) monolayer to covalently immobilize anti-CFP10 antibodies. The protein interaction with the antibody recognition platform was directly monitored and measured by cyclic voltammetry (CV) and electrochemical impedance spectroscopy (EIS). The immunosensors were characterized with atomic force microscopy (AFM) and Raman spectroscopy. After the analytical features optimization, a linear response from 0.5 ng ml-1 to 50 ng ml-1 of pCFP10:ESAT6, a limit of detection (LOD) of 4.80 ng ml-1 and a limit of quantification (LOQ) of 15.97 ng ml-1 were achieved, in a 4-hour essay time. The results indicate that the immunosensor is suitable, accurate, and selective for CFP10:ESAT6 protein detection, presenting exquisite features for point-of-care diagnostic applications in the future.

In Situ SAXS/UV-vis Nucleation and Growth of Gold Nanoparticles in HEPES buffer solution

e-mail: murillo.donizeti@ufabc.edu.br

The research about the mechanisms of gold nanoparticles synthesis has received great attention in scientific research because their wide variety of applications for biomedical treatments, such as: clinical diagnostics, disease prevention and drug delivery. One of the biggest challenges in the AuNP synthesis is the control of colloidal stability and monodisperse size distribution. In fact, the AuNPs regarding size, shape, size dispersity is determined since the first steps of gold ion reduction and nanocluster nucleation. In these steps the role played by gold ion hydration is crucial and not completely understood. The present study has a main goal to understand the role played by gold ion and gold nanocluster hydration in the process of gold nanoparticles synthesis. The strategy was to investigate the synthesis of gold nanoparticles in H2O and D2O, using 0.45 mM HAuCl4 and HEPES (0.25 and 30 mM) as reducing agent, in phosphate buffer pH 10. The synthesis was carried out by chemical route, without the addition of polymeric surfactants and additives that interfere in the morphology of the nanostructures. The isotopic substitution of the solvent clearly affected the properties of AuNPs. The specific structural, morphological, and optical properties of AuNPs synthesized in H2O and D2O were characterized in situ by ultraviolet-visible spectroscopy (UV-vis) and small angle X-ray scattering (SAXS) as a function of time and temperature. The results allow us to develop a model to describe the mechanisms underlaying the gold nanocrystal growing influenced by the solvent for a better control of AuNP synthesis.

Investigating Drug-Polymer Interactions of QPhNO2, PCL, PLGA, and PMMA using DFT Quantum Chemical Calculations for nanoencapsulation Applications.

EDWAR DAVILA MONTENEGRO[1], Jamylle M. Nunes[2], Eufrânio N. da Silva Júnior[3], Renata G. Almeida[4], Márcia S. Rizzo[4], Heurison Sousa Silva[5], Marcília Pinheiro da Costa[2]

e-mail: e.montenegro@ufpi.edu.br

This study investigates the interaction between QPhNO2 drug and polymers (PMMA, PCL, PLGA) for nanoencapsulation. The aim is to predict drug release factors and determine the optimal drug-polymer pair. Using DFT calculations, it is found that QPhNO2 interacts more favorably with PLGA than PCL. Molecular docking simulations and ab initio calculations predict molecular properties and therapeutic potential[1], highlighting computational chemistry''s value in drug development. Methods include Spartan''14 software and DFT approach (B3LYP, 6-311++G** basis set)[2] for molecular interaction analysis. ArgusLab 4.0.1 and Software Discovery Studio Visualizer support simulations. This research contributes to drug design and enhancement. QPhNO2, a potential anticancer drug, has limited clinical use due to solubility issues. Nanoencapsulation is promising for cancer drug administration using PCL, PLGA, and PMMA materials. Through computational methods, the study characterizes QPhNO2''s interaction with each polymer, predicting release factors and identifying the best pair. The results inform nanoparticle structure, impacting release mechanisms, and empha computational chemistry''s role in drug development and molecule characterization.

Investigating the Biodistribution of Magnetic Nanoparticles in Rat Models of Cirrhosis-Induced Hepatocarcinogenesis

Since magnetic nanoparticles (MNPs) presented the possibility of being used to liver diseases diagnose and treatment in recent years. This study aimed to inquire the influence of cirrhosis in the liver function. The distribution profile of MNPs was monitored by a real-time image acquisition approach after intravenous administration. Biodistribution profile was assessed based o Alternate Current Biosusceptometry (ACB) images obtained over regions of interest (ROIs) selected in heart and liver position according to previously decided anatomical references. The obtained signals allowed the quantification of pharmacokinetic parameters, inquiring that hepatic uptake was compromised during cirrhosis, which influences blood exchange between liver parenchyma and circulation. Kupffer cells remained constant during cirrhotic period, so the capillarization of hepatic sinusoids was considered responsible for the change in liver function.

Investigation of the electrospinning technique in obtaining nanofibers: synthesis, standardization and characterization

e-mail: bruno.melo@icf.ufal.br

Electrospinning is a methodology that uses a high voltage in obtaining nanofibers. In our study, the following parameters were observed: voltage of 15kV and 23kV, needle diameter of 0.7mm and 1.2 mm and distance to the 12 cm collector, in obtaining nanofibers of silver nanoparticles with red propolis from Alagoas (NPAg-RPA). Being the polymer matrix selected for the work, polycaprolactone (PCL), in silver concentrations of 1%, 2% and 5%. The characterization was performed by SEM, PXRD, TG/DSC, FTIR. Evaluating the applied voltage, the average diameters for the voltages 15 and 23 kV were found, being chosen the voltage of 15kV, for presenting better aspect in the diameter of the fibers obtained. The diameter of the needle at 1.2 mm was more efficient, providing a shorter time of contact of the solution with the atmosphere and presence of moisture. By SEM it was evaluated that higher concentrations of NPAg configured a reduction in fiber diameter and a greater uniformity of distribution. By PXRD, peaks related to PCL were observed both in its pure form and in the products associated with NPAg-RPA, as well as crystalline planes related to NPAg. By TG it was demonstrated that there were no changes in the decomposition of the products compared to the pure polymer. At the end, it was observed that the best parameters were voltage of 15kv and needle diameter 1.2mm. Through characterization techniques, it was observed that the nanofibers obtained demonstrate aspect ideas for a dressing, being a promising agent for research.

Cancer is one of the main threats to human health due to the large number of cases and high mortality rates. Although radiotherapy is the main course of treatment, it is not specific for tumor cells, affecting also healthy tissues. Radiosensitizers provide a novel and simple solution to this problem, since they increase the amount of radiation that a cell can absorb. Bismuth sulfide (Bi_2S_3) nanoparticles (Np) have interesting properties to be used as radiosensitizers and could be accumulated in tumors by EPR effect. However, the interaction between Np and blood compounds, resulting in the protein corona formation, can produce a Np stability loss, which influences the final treatment. In this study, we synthesized Bi_2S_3Np using a hot injection method and oleylamine as ligand, following a ligand exchange process. TEM images showed rods measuring on average 4.2nm in width and 27.4nm in length. The ligand was successfully exchanged by polyvinylpyrrolidone (PVP) or polyethyleneglycol (PEG), confirmed by Diffuse FTIR and TG-DSC analyses. The Bi_2S_3-PVP and Bi_2S_3-PEG hydrodynamic size were 142.1 nm and 124.4 nm, determined by DLS, and their Z potential were -5.24mV and -1.15mV respectively. To study the protein corona formation, Bi_2S_3-PVP or Bi_2S_3-PEG Np were incubated in cell culture medium DMEM supplemented by 10% FBS (DMEM-FBS) and artificial blood plasma fluid (aBPF), for 15 min to 48 h at 37 ℃. According to the hydrodynamic sizes and Z potentials, the Np-protein corona assembly was stable during the incubation time. The average size in DMEM-FBS increased to 206.7 nm and 180.6 nm and the Z potential decreased to -11.8mV and -20.4mV for Bi_2S_3-PVP and Bi_2S_3-PEG Np, respectively. In aBPF, the size was 160.1 nm and 149.8 nm and the Z potential was -11.8mV and -15.0mV for the same Np. Our findings demonstrate that the protein corona formation enhances the ability of the Np to interact with cells in vitro and to move through the bloodstream for further applications in vivo.

LIPID TAIL DEPENDENCE ON THE EFFECTS OF THE PESTICIDE ETHEPHON IN PHOSPHATIDYLCHOLINES MODEL MEMBRANES

[1]Universidade Estadual Paulista "Júlio de Mesquita Filho" - Faculdade de Ciências e Tecnologia - Campus de Presidente Prudente (*Physics*) , [2]Universidade Estadual Paulista "Júlio de Mesquita Filho" - Faculdade de Ciências - Câmpus de Bauru (*Physics*)

e-mail: jaqueline.nascimento@unesp.br

Ethephon is a pesticide largely used in Brazilas a growth regulator, and in fruit maturation. Studies related to the long-term exposure effects of the ethephon in humans through water and food ingestion are sparse and inconclusive. For this reason, we investigated the effects of the ethephon in Langmuir monolayer and lipid bilayers (LUVs and GUVs) as bioinspired c system of the plasma cell membrane, since this organelle is responsible for maintaining cell integrity and actsas a selective barrier to most external agents. The phospholipids used DPPC, POPC and DOPC differ in terms of the number of unsaturation present in the tail of hydrocarbons (0, 1 and 2, respectively) and were chosen because they belong to the phosphatidylcholine group, majority present in most cell membranes. Ethephon interacts at the air/water interface with the POPC and DOPC, causing displacement in the isotherms. The in situ infrared reflection absorption spectroscopy with polarization modulation (PM-IRRAS) spectra indicated changes in choline and phosphate head groups of the lipids in presence of ethephon. However, the band referring to stretching of the unhydrated carbonyl group (C=O) is displaced only for POPC. This phospholipid is sensitive to hydrolysis reactions precisely with bond breakage in the carbonyl group. Ethephon, in turn, seems to be favoring this breakdown, much more evident than the peroxidation reactions commonly seen for DOPC. Ethephon reduced the Zeta potential of the POPC LUVs, therefore confirming preferential interaction in the polar head group moiety of the lipids. Microscopy images revealed that only POPC GUVs suffered considerable damage in the presence of ethephon, causing loss of phase contrast as well as vesicle bursts. This work highlights the importance of understanding the behavior of ethephon in structures that preserve chemical structure of the cell membrane, being good indicators of its action in biological processes.

e-mail: vitoriaantunes@outlook.com.br

Biogenic nanoparticles have less residual toxicity, better stability, and the possibility of size control. They feature a coating of proteins and metabolites (capping) derived from the organism used in the process, and this capping contributes to the stability and biological activity. The plant *Achillea millefolium*has shown to be a promising reducing and stabilising agent in the biogenic synthesis of silver nanoparticles (AgNP) with antimicrobial potential and low toxicity, being a possible source of new drugs. The synthesis of biogenic AgNPs was characterised using dynamic light scattering - DLS and nanoparticle tracking - NTA technique their cytotoxic potential (MTT Test) and their activity in controlling pathogens (Disc diffusion and Minimum Inhibitory Concentration - MIC) were also evaluated. AgNPs had a polydispersity index of 0.565 ± 0.006, a zeta potential of -23.4 ± 0.5 mV, a mean sizeof 77.2 ± 0.9 nm and a concentration of 7.38 x 1010 NPs/mL. MTT did not show IC50 valuesin any strain, indicating low toxicity. The disk-diffusion test and MIC showed the antimicrobial potential of AgNPs on the tested microorganisms. Therefore, they may be a viable option for application in the control of pathogens, with the absence of cytotoxic effects at effective concentrations, aiming at their future application in the health area. New studies must be carried out to obtain a safe final material.

e-mail: gustavoo.existe@gmail.com

The pursuit of ideal biomaterials that perfectly match the building blocks of organs and tissues and that are well recognized and integrated with the microenvironment surrounding the tissues and cells is a never-ending challenge[1]. CS provides the tissue with a good resistance to compression and exhibits anti-inflammatory and anti-catabolic activity. Present in large quantities in native ECM and on the surface of cells, this polymer enhances growth and contributes to neurotrophic factors. CS is an important component in wound healing, promoting cell adhesion and cell proliferation[2]. Herein, we disclose a versatile and facile catalyst-free click chemistry for the generation of an innovative hydrogel by combining chondroitin sulfate (CS) and polyethylene glycol (PEG). The hydrogel demonstrated not only enhanced blood perfusion and an increased number of blood vessels, but also desirable fibrous matrix orientation and normal collagen deposition. Taken together, these results demonstrate the potential of the hydrogel to improve wound repair and hold promise for in situ skin tissue engineering applications.

After the administration of magnetic nanoparticles (MNPs) in an organism, several parameters including retention and elimination profiles, physiological parameters and possible interactions must be assessed. Alternate Current Biosusceptometry (ACB), a biomagnetic detection system, can be used to detect and quantify MNPs. The study aimed to evaluate MNPs clearance and biodistribution profiles over long-time in vivo analysis and determine the elimination time, accessed by the association between ACB and manganese ferrite (MnFe2O4) nanoparticles. Samples of liver, lungs, spleen, kidneys, heart, and blood were collected over 60 days for biodistribution and elimination analysis. During the assessment period animal's feces were also collected. It was possible to notice a higher uptake by liver and spleen due to intrinsic retention and uptake factors. Over these 60 days we observed an absence of MNPs in spleen and significant decay in the liver. It was also possible to determine the MNPs half-life trough by the liver and spleen elimination. The results showed a decay on the concentration profile over the time, which suggest that in addition to elimination by feces, there is an endogenous mechanism of agglomeration or metabolization involved, resulting in loss of the signal intensity.

Melatonin loaded polymeric nanoparticles for glioblastoma therapy

Natalia Sanchez Moreno[1], Iasmin Gabrielli da Silva[2,1], Natália Noronha Ferreira[1], Valtencir Zucolotto[1]

[1]Nanomedicine and Nanotoxicology Group, Physics Institute of Sao Carlos, University of Sao Paulo, 13566-590, Sao Carlos, SP, Brazil, [2]Universidade Paulista

e-mail: natalia.smoreno@gmail.com

Glioblastoma (GBM) is a highly malignant brain tumor with an elevated risk of recurrence and mortality. Current treatment options, s Current treatment options, such as a therapeutic regimen applying temozolomide (TMZ), show limited efficacy due to the invasive and heterogeneous nature of the tumor and the development of resistance mechanisms[1]. Melatonin (MLT) has shown promising anticancer activity in GBM, due to its ability to reduce the tumor cell proliferation, and modulate different signaling and biological processes.[2]In this study, we developed a new approach for GBM treatment by encapsulating MLT in poly(lactide-co-glycolide) (PLGA) nanocarriers. These nanosystems have shown an encapsulation efficiency of 94%, a diameter of 112 ± 5 nm, a polydispersity index (PDI) of 0.164 ± 0.015, and a zeta potential of -14 ± 2 mV, which are suitable physical properties fordrug delivery intended nose-to-brain approach. Our novel anticancer system may offer a promising therapeutic opportunity for GBM treatment.

e-mail: juliamargatho@usp.br

Gold nanoparticles in the form of nanorods (AuNRs) have shown promising potential as contrast agent in photoacoustic imaging due to their localized surface plasmon resonance (LSPR) which allows them to efficiently absorb light in the near-infrared region. However, it is crucial to evaluate the impact of commonly used emitters, such as LEDs and lasers, on photoacoustic signal intensity a structural property of AuNRs. To this end, AuNRs of different lengths were synthesized and characterized by spectroscopies, dynamic light scattering, nanoparticle tracking analysis, and transmission electron microscopy. The photoacoustic signal was evaluated for different particle sizes and concentrations using both LED and laser emitters. The experimental results revealed that the intensity of the photoacoustic signal was dependent on both length and concentration of AuNR. In addition, significant morphological changes were observed upon irradiation of AuNRs with a laser, as compared to LED. This study provides new insights into the signal parameters of AuNRs in photoacoustic imaging and their interaction with AuNRs during irradiation. Notably, the study suggests that LEDs may have advantages as emitters for photoacoustic imaging using AuNRs as contrast agent.

Monolayer magnetic nanospheres have selective binding that allow the concentration of low-abundance proteins from blood serum

Jemmyson Romário de Jesus[1], Edileuza Marcelo Vieira[1] [1]Fundação

Universidade Federal de Viçosa (*Departamento de Química*)

e-mail: jemmyson.jesus@ufv.br

The efficiency of magnetic nanosphere (Fe304) coated with L-histidine (L-his) was evaluated to enrich proteins of low-abundance in human serum that are potentials biomarkers of human disease. The chemometric analysis provided optimal conditions to concentrate low-abundance proteins, reducing the dynamic range of protein levels in the serum sample. Three independent factors (temperature, mass ratio and pH) were tested. The optimal condition achieved was using temperature (42°C), ratio (3:1, nanomaterial/sample) and pH (5.5). The kinetic study revealed that the adsorption of proteins on the surface of the monolayer magnetic nanosphere follows a pseudo-second order model with R2=0.9153. Adsorption isotherm experiments revealed high capacity of protein adsorption on the surface of the nanosphere, indicating a maximum theoretical adsorption capacity (qmax) of 123.45 mg g-1. The efficiency of enrichment of low-abundance proteins in the serum sample was evaluated by gel electrophoresis (SDS-PAGE). Furthermore, when compared to the method using organic solvent (acetonitrile), Fe304@L-his showed adequate efficiency to simplify the serum sample. Using MALDI-TOF/TOF, approximately 50 proteins were identified using Fe304@L-his. As a proof of concept for this study, patients with bipolar disorder and healthy controls were discriminated using the magnetic nanosphere as an adsorbent in the sample preparation step. These results show that Fe304@L-his can be a fast, robust, and simple alternative to enrich low-abundance proteins in human serum, emerging as an important strategy in the search for biomarkers of human diseases.

Magnetic nanoparticles (MNPs) have broad utilization in biomedicine, such as drug delivery, magnetic hyperthermia (MH), and as contrast agents for different imaging modalities. However, their effectiveness as a contrast agent for ultrasound and photoacoustic imaging (PAI) is limited. This study aimed to evaluate the effectiveness of coating magnetic nanoparticles with natural rubber latex (NRL) to overcome this drawback. Furthermore, the impact of NRL coating on MNPs'' heating mediator potential in MH was investigated. MNPs were synthesized via the coprecipitation method, utilizing three NRL coating volumes (0, 100, and 400 μL) [1]. The MNPs were submitted to several diagnostic techniques, such as magneto-motive ultrasound (MMUS) and photoacoustic imaging, in addition to being used in magnetic hyperthermia. The average size of the MNPs ranged from 10 to 20 nm, as confirmed by X-ray diffraction and transmission electron microscopy. Magnetic hysteresis curves indicated superparamagnetic samples. NRL-coated MNPs showed higher saturation magnetization, improving MMUS displacement, and increased optical absorbance, resulting in improved PA image quality. SNR values for the PA images were 261, 481, and 650 for uncoated MNPs, NRL-100, and NRL-400, respectively. For MH experiments, Specific Loss Power values of 57, 43 and 40 W/g were obtained using 0.25% (wt.) of MNPs coated with 0, 100 and 400 μL of NRL. These findings suggest that NRL-coated MNPs are promising candidates for contrast agents in both MMUS and PA imaging, as well as heat mediators for MH in tumor treatment.

Magnetic resonance imaging (MRI) is one of the current imaging techniques for cancer diagnoses. Despite having high resolution, it has low sensitivity. This limitation can occur even when contrast agents (CAs) are used. In these cases, the concentration of the CAs is not enough to show differentiation between healthy and pathological tissues [1]. One strategy that has been used in the past years is the association of CAs molecules to nanoparticles, such as quantum dots (QDs). QDs usually have a typical size ranging from 2 to 10 nm and unique optical properties. Besides, they have active surface for (bio)conjugation, allowing the attachment of CAs and biomolecules. Folic acid has been used for specific targeting of cancer cells due to the overexpression of folate receptors on most of these cells [2] In this work, we prepared AgInSe2 QDs in an aqueous medium, using a one-pot method and mercaptosuccinic acid as the stabilizer. These QDs were conjugated to thiolate DOTA complex derivatives and folic acid molecules, through dative bonds. The preliminary results showed a loss of around 50% of the emission intensity of the QDs after the conjugation procedures. And relaxometric studies showed an increase in the relaxivity values of these nanosensors, compared with the free Gd-DOTA complex in solution. Nevertheless, the systems developed show potential to be used as CAs for cancer diagnosis.

Amphiphilic polymers have been attracting great interesting in pharmaceutical formulations due to their self-aggregation ability, which can promote nano or microparticles systems in an aqueous medium [1]. Poly(Z-L-Lysine) (PZLL) is a polypeptide in which the presence of aromatic carbamate (Z) can result in a conjugation with lipophilic drugs, and contribute for improving the polysaccharide structing making it appropriate for biomedical applications [2]. The presence of a cationic group in a copolymer can promote the sensibility to a pH change under solution, resulting in controlled release in drug delivery systems [2]. In order to compare the amphiphilic copolymers with and without the cationic properties, the amphiphilic pullulan was prepared by two different routes, first it was reacted with 2-Chloro-N,N-diethylethylamine (DEAE), resulting in PULL-DEAE, followed by the ring opening copolymerization (ROP) of carbobenzyloxy-l-lysine N-carboxyanhydride (Lys(Z)- NCA), obtaining PULL-DEAE-g-PZLL. The same copolymerization was applied, however to unmodified pullulan, resulting in the second amphiphilic copolymer, without the cationic group, PULL-g-PZLL. The final product was nanoprecipitated by dialysis method and the particles were evaluated by, particle size, particle distribution, zeta potential and sensibility under different pHs. The polymers resulted can be applied in the biomedical field, in different areas, according to the final properties obtained, besides, it can be used to encapsulate different actives.

Obesity is a chronic disease characterized by excess body fat associated with subclinical inflammatory responsible for damages, such as micronutrient deficiencies such as retinol [1]. Beta-carotene is a precursor of retinol but is unstable to environmental conditions and can be preserved and/or enhanced functionality by nanoencapsulation [2]. The study evaluated the effect of a crude extract rich in β-carotene from Cantaloupe melon (Cucumis melo L.) (CE) nanoencapsulated (EPG) on food intake, weight, and hepatic retinol in Wistar rats with diet-induced obesity. CE was nanoencapsulated in porcine gelatin by O/W emulsification technique and characterized by SEM, Laser Diffraction, FTIR, and carotenoid encapsulation efficiency (EE) determine whether the new batch obtained was as in previous studies. Wistar rats with obesity induced by a high glycemic index and high glycemic load diet (HGLI diet) were divided into three groups (n = 5): HGLI diet + water, HGLI diet + CE (12.5 mg/kg), and HGLI diet + EPG (50 mg/kg containing 0.62 mg/ml of CE) administered by gavage (1mL) for ten days evaluated for dietary intake, weight, and hepatic retinol. EPG presented a smooth surface, mean diameter of 80 (8.59) nm, and polydispersion index of 0.47 (0.09), new chemical interactions, and EE of 95.20% (0.74), as those obtained in previous studies. Animals treated with EPG showed a lower dietary intake ($p < 0.05$) and no significant change in the animal's weight in the groups. EPG-treated group had higher hepatic retinol ($p < 0.05$) [266 (45) μg/g] than the untreated [186 (23.8) μg/g] and treated with CE [175 (8.08) μg/g]. Nanoencapsulation promoted protection and contributed to the bioactive compound's absorption, allowing a higher concentration of retinol in the liver of obese animals.

Nanostructured Materials Based on the Self-Assemblyof the Antidiuretic Peptide Desmopressin

Ana Beatriz Caliari Souza[1], Clovis Nakaie[2], Emerson Rodrigo da Silva[2] [1]Universidade

Federal de São Paulo, [2]Universidade Federal de São Paulo (*Biofísica*) *e-mail:*

ana.caliari@unifesp.br

Desmopressin acetate (DDAVP) is a synthetic analog of the antidiuretic hormone vasopressin largely employed as a first-line pharmacological approach for urinary diseases such as diabetes insipidus and nocturia. Herein, we aimed to develop nanostructured materials with antidiuretic properties based on the self-assembling capabilities of DDAVP. In addition, we provide information about its structure, from the molecular level to the nanometer range. Also, we investigate the nanoparticle' s cytotoxicity effects. The structural analyses were performed through spectroscopic techniques (fluorimetry and circular dichroism), whereas morphology assays were carried out using atomic force microscopy. The cytotoxicity was determined by the MIC value. DDAVP was found to form nanometric aggregates at critical concentrations near to 1 mg/ml, with β-sheet conformations dominating the secondary structure of the aggregates. Quenching of tyrosine emission indicated a major role of hydrophobic domains in the self-assembly. The interaction of peptides with lipid membranes was also demonstrated, showing that their secondary structure is modified in the presence of membranes, and interaction with lipid bilayers being driven by hydrophobic domains. Cytotoxicity was not observed even in high concentrations above the CAC, which did not influence in the microorganisms growth. We demonstrated the fabrication of ordered nanoassemblies based on desmopressin, which is stabilized by β-sheets. It was also verified that the nanoparticles interact with lipid membranes, suggesting they can associate to cell membranes. The nanoparticles were not cytotoxic, showing its potential biomedical use. To our knowledge this is the first study reporting the production of nanostructured materials from peptides endowed with antidiuretic activity.

Several strategies have been used to overcome the therapeutic limitations of Resistant tuberculosis (TB) and multidrug-resistant TB, however, issues related to lack of effectiveness are still a concern [1]. As an alternative, nanotheranostic systems have been used to modulate the resistance of some TB drugs, which is possible due to their reduced that allows for different delivery mechanisms when compared to free drug. In addition, the use of theranostic nanosystems allows the combination of different therapies, such as the use of a radiation source to promote photothermia. In this study we developed a nanotheranostic system for TB therapy based on the encapsulation of standard anti-tuberculosis drugs, isoniazid and rifampicin, in a PLGA system containing AuNRs to promote phototermia (named PLGA/ISO-RIF/AuNRs). The physicochemical analysis revealed a spherical morphology with hydrodynamic of 253 ± 9.3, a polydisperse index (PdI) of 0.167 ± 0.044 and a potential zeta of +32 ± 3 mV. The encapsulation efficiency was estimated at ca. 75% for both drugs. PLGA/ISO-RIF/AuNRs nanoparticles were administrated in murine (BMDM) and human (THP1) macrophages showing synergy in the results compared to PLGA NP or PLGA/ISO-RIF NPs.

Acknowledgments: Financial support from CNPq is gratefully acknowledged.

The development of alternative (and antibiotic-free) antibacterial and antibiofilm agents is an important strategy to prevent bacterial resistance to antibiotics. With this aim, the production of mixed oxides has been explored by incorporating silver nanoparticles in titanium dioxide as an antibacterial agent with behavior dependent on the concentration of silver, for the following step of incorporation into the skin of Nile tilapia [1]. Three experimental systems were evaluated: pure titanium dioxide (TiO_2), TiO_2 with 2% by weight of $AgNO_3$ precursor (TiO_2/Ag2%) and TiO_2 with 10% by weight of $AgNO_3$ precursor (TiO_2/Ag10%). The antibacterial and antibiofilm activity was tested against the Staphylococcus aureus strain (ATCC 25923) which is a biofilm-producing bacteria. The influence of silver concentration was confirmed through the results of microdilution tests in broth, kill time curve and diffusion in agar, in which the pure titanium dioxide (TiO_2) did not show antibacterial activity, but the TiO_2/Ag 2% sample exhibited a minimum bactericidal concentration (MBC) of 6.25 mg/mL, kill time in the order of 45 min and inhibition halo of 21.6 mm; and the sample with the highest silver content (TiO_2/Ag10%) had a MBC of 3.13 mg/mL, characteristic kill time of 30 min and inhibition halo of 23.81 mm. In addition to showing the best results in terms of antibacterial activity, samples prepared with high concentrations of silver (10% by weight of the $AgNO_3$ precursor) showed a good antibiofilm response. These results indicate that tilapia skin modified with mixed oxides acquires antibacterial behavior and can be exploited as a xenograft.

Paclitaxel encapsulated in PLGA nanoparticles for lung cancer therapy

e-mail: camilafrodero@hotmail.com

Lung cancer is a type of cancer that has a high occurrence and fatality rate in Brazil and globally. It is usually detected in advanced stages, which makes its prognosis difficult. In this context, researchers have explored novel proposals using nanotechnology to enhance the effectiveness and bioavailability of drugs for treating this type of cancer. In this studywe have developed a nanostructured system from poly(lactic acid-co-glycolic acid) (PLGA) to release paclitaxel (PTX) in the treatment of lung cancer to modulate or enhance the action of this drug. We used a simple emulsion technique to develop polymeric nanoparticles (NPs) containing PTX. The NPs had an average diameter of 162 nm, polydispersity index (PDI) of 0.168 in, and zeta potential of -23 mV. Further physicochemical analyses are underway to improve the characterization of the NPs before subsequent viability and cellular internalization assays. The development of these nanosystems is significant in the pursuit of suitable therapeutic approaches for managing lung cancer.

Photodithazine-nanoclay composites to improve antimicrobial activity.

e-mail: isabella.lopes@usp.br

Advanced nanomaterials for drug delivery systems are the main focus of numerous research groups and, its application on drug resistance problem is probably the biggest challenged faced by scientists in the field. Indeed, in 2018, WHO declared the antimicrobial resistance as ‘(…) one of the top 10 global public health threats facing humanity’, along with a similar problem in cancer treatment: the chemotherapeutic drug resistant cells. In both cases, photoinactivation systems [1] and photodynamic therapy (PDT) can overcome the problem of drug resistance when compared to the traditional approaches. For PDT, which has been shown to be efficient against some Gram (-) and (+) bacteria [2], more robust and efficient molecules that can act as photosensitizers (PS) are still needed for the improvement of the technique. In this work, the second-generation PS derived from chlorophyll, photodithazine (PDZ), was submitted to a set of physiochemical variations (pH 2, 5, 7 and 10, and concentrations of 2.5, 6, 12, 16, 22, and 25 μg/mL) to promote new aggregation states with the aim of improving its antimicrobial activity. The aggregated states of PDZ were characterized by photoluminescence and photoluminescence excitation spectroscopies, showing different conformations at basic and at acidic pH, but not changing significantly with the increase in concentration. The acidic forms, which showed higher activity against both bacterial strains, were used to build composites with halloysite nanoclays, which showed a significant improvement in antimicrobial activity against S. aureus and decreased the growing rate of E. coli cells. The effect of the composites will be discussed in light of the photophysical behavior of PDZ and the near field effect.Acknowledgements:CAPES-Brazil-Finance Code 001, FAPESP 2022/08842-0.References:[1] A. e-mail: vasconcelosir2@gmail.com

Photothermal therapy (PTT) is one of the most recent methods in the treatment of cancer, being little invasive and of low complexity. Being incipient, the production of materials with high efficiency is necessary for the technique progress. This work report the electrosynthesis of bismuth silver selenide nanocrystals ($Bi_2S_xSe_{1-x}$) stabilized by 3-mercaptopropionic acid and evaluated the performance of the material to photothermic applications. The quantum dots alloys were electrosynthed in aqueous medium by the direct reduction of Se0 and S0 in the electrochemical cavity cell.[1] The nanoalloys were obtained by adjusting the Se/S molar ratio (Se/S = 0, 0.2, 0.4, 0.6, 0.8, 1). For photothermal properties, was modulated the range of emission and photothermic response under laser excitation, λexc = 785 nm. The zeta potential mesurements indicated the negative charge associated with the particles, all most negative than −30 mV, indicating the relative stability. The samples with concentration of 61 µg/mL, when irradiated with laser 785 nm and laser potency 1 $W.cm^{-2}$, presented response between 44.4°C for 36.8°C Bi_2S_3. All chalcogenides' alloys presented increase of photoresponse, given the best photoresponse for the alloy of $Bi_2(S_{0.4}Se_{0.6})_3$, equal to 44.4°C. This behavior was associated with the structural and electronic defects, by the substitution of Se^{2-} positions by S^{2-} ions, and the intrinsic difference of orbital energies. Leading to vibrational effects generated by lattice phonons. Thus, evidence the increase of photothermal response with the chalcogenide's alloys. The proposed system represent a promisor group of nanoparticles with photoresponse, candidate to photothermal therapy of cancer.

e-mail: brunalorenamarques@gmail.com

The encapsulation of a lipophilic component (quinoa oil) has been used for various factors, such as the preservation and enhancement of bioactive properties, and improvement of their incorporation into a product. The aims of this work were the production and characterization of quinoa oil encapsulated in porcine gelatin (OG) and combination with whey protein isolate (OWG), using oil/water and multilayered emulsification. The characterization was performed by Dynamic Light Scattering (DLS), Fourier Transform Infrared Spectroscopy (FTIR), Zeta Potential at different pH values and the evaluation of the encapsulation efficiency. The antioxidant and antimicrobial activity of samples were performed by the methods: total antioxidant capacity (TAC), ion chelation, and minimum inhibitory concentration (MIC). The encapsulation efficiency determines the oil content (%) was successfully encapsulated at 74.13% and 83.08% for the OWG and OG, respectively. The FTIR of the OG showed an interaction between quinoa oil and gelatin indicating encapsulation of quinoa oil. OWG conferred greater protection to the oil due to interactions between porcine gelatin and whey protein, making encapsulation more efficient. The particle is 249 nm to OG and 152 nm to OWG. The zeta potential at different pHs showed that as the pH decreases, there is an increase in the zeta potential (+21 mV) considered moderately stable. The encapsulated quinoa oil OG e OWG (38,61 and 41,81 μg EAA/g), respectively, showed higher total antioxidant activity when compared to the crude oil (25,64 μg EAA/g), however in the chelation test of iron ions there was no significant difference. The MIC of *Staphylococcus aureus, Burkholderia cepacia e Burkholderia multivorans*were above10 mg. mL^{-1}. The results indicate that the encapsulation of quinoa oil shows potential for various biological applications, enhancing the activities of antioxidants e antimicrobial of quinoa oil.

e-mail: anatognoli@hotmail.com

While mass vaccination against the Sars-CoV-2 virus is a promising strategy to control the COVID-19 pandemic, there is still a need to develop effective treatment options for individuals who cannot be vaccinated or for future outbreaks caused by novel Sars-CoV-2 strains. Remdesivir (RDV), a monophosphate prodrug of nucleoside analog GS-441524, was the first drug approved for the treatment of moderate to severe COVID-19. However, properties such as low solubility, high effective dose concentration, low half-life time, and side effects limit its clinical application. To circumvent this problem, we developed polymeric nanoparticles loaded with the drug RDV by nanoprecipitation methods. The nanoparticles were functionalized with dextran and chitosan to modulate cell uptake. The Remdesivir-containing nanoparticles exhibited a diameter of 120 nm, zeta potential of - 35 mV, and encapsulation efficacy of ≈ 90%. Cell internalization and cytotoxicity assays revealed that the NP@RDV significantly accumulate in different cell lines within 2 h of treatment and displayed less toxicity compared to free RDV. These results indicate that NP@RDV represents a potential new candidate for COVID-19 treatment.

Size-Dependent Synthesis and Characterization of Silica Nanoparticles: Exploring the Role of Particle Size on Material Properties

Fernanda Milanez Brugnari[1], Daniella Lury Morgado[1], Arthur Martins Gabriel[1], Guilherme Augusto Arioli[1], Caue Ribeiro de Oliveira[2], Emerson Rodrigues de Camargo[1]

Due to their exceptional combination of advantageous properties such as low toxicity, high biocompatibility, and biodegradability, mesoporous silica nanoparticles (MSNs) have gaineda prominent position in the scientific community for their potential applications in various fields. Silica (SiO_2) has potential applications in the biomedical field for drug delivery, tissue engineering, and diagnostic imaging, and in the environmental field for water treatment, air purification, and soil remediation. During the synthesis of MSNs, it is possible to control some parameters by adjusting the amounts of tetraethyl orthosilicate (TEOS), ammonia, andwater. It must be pointed out that the control of the morphology, particle size, and porosityof MSNs affect both the rate of release of substances and the total amount released. In thiswork, using the Stöber method, the MSNs were synthesized by hydrolysis and controlled condensation of TEOS in an alcoholic medium. The obtained nanoparticles were characterized in relation to the particle size and morphology through scanning electron microscopy (SEM), transmission electron microscopy (TEM), and dynamic light scattering (DLS) techniques. The MSNs were characterized by solid-state ^{29}Si nuclear magnetic resonance (NMR). Adsorption and kinetic studies of dye onto MSNs were also conducted. The results indicated that the MSNS was successfully obtained. Based on the results of this work, the MSNs may be used in a variety of fields, especially in hormonal monitoring of reophilic fish of the genus Brycon.

Studying the interaction of octaketide cytosporone-bwith Langmuir thin films as cell membrane models

Guilherme Nunez Jaroque[1], Patricia Sartorelli[1], Luciano Caseli[2]

[1]Universidade Federal de São Paulo (*Química*) , [2]Universidade Federal de São Paulo (*Department of Chemistry*)

e-mail: guilhermejaroque@gmail.com

The study of compounds with biological action on cell membrane models enables us to predict the interactions at the molecular level. Such interactions can be investigated using Langmuir thin films of phospholipids, which are monolayers assembled at the air-water interface that can mimic one side of the cell membrane. This work aims to study the interaction of Cytosporone-B (Csn-B), a secondary metabolite isolated from the fungus Phomopsis sp., with Langmuir monolayers composed of the lipids dipalmitoyl phosphatidylcholine (DPPC), palmitoyloleoyl phosphatidylcholine (POPC), dipalmitoyl phosphatidylethanolamine (DPPE), dioleoyl phosphatidylethanolamine (DOPE), dipalmitoyl phosphatidylserine (DPPS) and palmitoyloleoyl phophatidylserine (POPS), major lipids found in erythrocyte cell walls (both choline phospholipids), in bacteria cell walls (both ethanolamine phospholipids), and in the cell membranes in the early stages of apoptosis (both serine phospholipids), respectively. Csn-B shifted the isotherms to lower areas, pointing to monolayer condensation, which suggests that the Csn-B interacted with the polar head of the phospholipids, reducing their lateral repulsion. AFM images showed that the different monolayer compositions adhered in different ways to the substrate after the addition of Csn-B. BAM images showed the formation of domains and discrete clusters after the addition of Csn-B. PM-IRRAS spectra showed changes in the relative intensity of bands related to the stretching of the methyl group present in the large alkyl chains of the lipids, as well as in the phosphate and carbonyl group bands, indicating not only interaction with the polar head but also the distortion of tilting of the alkyl chains. In conclusion, Csn-B changed the thermodynamic and morphological properties of lipid monolayers, where it is possible to notice that the film''s chemical composition modulates the interaction with cell membrane models.

The nanotechnology field has been growing in the past decades, improving studies of several compounds. Drug delivery systems are being largely used, whose objective is to increase pharmaceutical substances efficacy, and this may include a more selective distribution within the sick organism, the molecules liberation time fine-tuning and/or attenuation of adverse effects. Drugs are nanoencapsulated within synthetic origin or biodegradable structures, necessarily compatible with the active principle. Cubosomes are a hotspot, which are complex nanostructures that successfully encapsulate hydrophilic and hydrophobic activities. The main objective is to study the effect of the antineoplasic activity against cervical cancer cells (HeLa) and human epidermal keratinocyte (HaCat), the synergic/antagonistic effects of drugs, cubosomes synthesis and characterization for further encapsulation of actives inside them. The drugs are cisplatin, vemurafenib and curcumin. In this work, we will broaden our knowledge of the antineoplasic activity of these compounds, testing them on HeLa and HaCat cells, and quantifying the post-exposure cell viability. The cubosomes were synthed with phytantriol and tested by dynamic light scattering (DLS), nanoparticle tracking analysis (NTA) and cell viability test. The cell viability test showed promising results at a dosage of 0,01 mg/mL in both cell lineages. The cubosomes had a hydrodynamic diameter of 197(5) nm, polydisperse index of 0,05(0,05) and a concentration of 5,2 x 10^{12}particles/mL. The encapsulation looks promising and the cubosomes were efficiently synthed and seem to be stable.

e-mail: thayaneoliveira@ufpi.edu.br

The properties of Magnetic nanoparticles (MNPs) MNPs allow the absorption, transport and controlled delivery of drugs to a specific body-place with high efficiency by means of changing the intensity of a magnetic field [1]. Among MNPs, cobalt ferrite (CoFe2O4) is a promising material for drug delivery, due to its physical-chemical and mainly magnetic properties [2]. Thus, in the present work, samples of CoFe2O4 doped with copper and nickel were obtained from two synthesis routes: coprecipitation and sol-gel, using different percentages of doping and subsequently thermally treated at temperatures of 700, 800 and 900 °C. The formation of a single CoFe2O4 phase with a cubic structure was observed in all samples treated in the range of 700 to 900 °C. The magnetic behavior of the samples was analyzed through VSM. The infrared spectra indicate the presence of modes associated with cobalt ferrite. One can verify the active modes of the spinel structure through the Raman spectra. Based on the achieved results, it is concluded that the synthesis routes were efficient for producting cobalt ferrite NPs, which can be used later in the delivery of drugs.

e-mail: tatiane.britos@unifesp.br

Motivated by the broad range of applications in the technological, industrial, and biomedical fields, we developed mechanisms for synthesizing superparamagnetic iron oxide nanoparticles (SPIONs) for biomedical use [1,2]. In this research, we synthesized, characterized, and evaluated the cytotoxicity of this nanomaterial, comparing and investigating its characteristics with the available literature to improve its biocompatibility and suitability for nanomedicine applications.Synthesis is critical in obtaining the necessary properties for the objective application of nanomaterials. Among the various existing methods, we selected co-precipitation because it is a simple and cost-effective method that produces nanomaterials compatible with biomedicine [3]. We synthesized SPIONs by mixing ferric and ferrous chlorides in an aqueous solution and precipitated them using ammonium hydroxide. To prevent agglomeration of nanoparticles and facilitate targeting of specific sites using an external magnetic field, we functionalized the SPION surface with organic ligands (Cysteine or Glutathione - molar ratio, SPIONs:ligand = 1:5) that contain a functional group (-SH).We characterized the particles using Fourier transform infrared spectroscopy (FTIR), UV-Vis spectroscopy, Microscopy RAMAN, X-ray powder diffraction (XRPD), dynamic light scattering (DLS), and SQUID magnetic measurements. Finally, we evaluated the cytotoxicity of nanoparticles in vitro using healthy and tumor cell cultures.

Cancer is one of the most complex public health problems in the Brazilian health system. In 2020, more than 19 million cancer cases were diagnosed. Melphalan hydrochloride (MEL) is a chemotherapeutic drug with antitumor activity known for its groups of alkyl agents. During the last decades, MEL has been administrated to patients with breast and ovarian cancer, mainly to treat multiple myeloma. However, its oral administration has some limitations as pre-systemic elimination and incomplete toxicity [1]. Herein, we determine the crystal structure of MEL hydrochloride using X-ray powder diffraction data and a simulated annealing procedure. MEL crystallizes in a monoclinic crystal system ($P2_1$). A rational screening conducted in Mercury (CSD-Materials) indicates the possibility of using different synthons to obtain new crystalline forms to improve the drug' s performance and the compound' s-controlled release. As MEL displays low water solubility, new co-crystal formsare of interest. The milling process is performed using mortar and pestle (manual milling)and ball mill (mechanochemical). In both procedures, stoichiometric mixtures of MEL are combined with some conformers (L-glutamic acid, Lactose, Saccharin, and Caffeine), which Mercury indicates as possible synthons.

Pancreatic cancer occupies the fourth position in deaths caused by malignant neoplastic diseases and exhibits high metastasis progression rates [1]. In modern nanomedicine, theranostic nanocarriers are in the front-line search for innovative solutions to improve the efficiency of traditional therapeutic methods, such as chemotherapy. One of the most promising theranostic nanosytems is based on calcium orthophosphate (CaP) nanoparticles (NPs), which exhibit high biocompatibility, loading efficiency of drugs, and self-activated luminescence [2,3]. This study aims to synthesize luminescent CaP NPs and use them for the controlled delivery of gemcitabine (GEM), which is one first line therapeutic agent often administered to treat pancreatic cancer. The CaP phase and the presence of GEM on the NPs were confirmed via FTIR spectroscopy. The typical broadband photoluminescence (PL) emission of CaP centered at 580 nm (λexc = 405 and 488 nm) was observed via PL spectroscopy. Size of NPs was estimed as 206.1±19.37 nm and 206.3±68.0 nm via DLS andNTA techniques, respectively. The Zeta potential decreased from −1.88 ± 1.21 mV to −13.0 ± 0.153 mV due to GEM encapsulation. The GEM loading efficiency of 9.8% was determined by UV-Vis spectroscopy. The cell viability of our NPs was probed via MTT assay with PANC-1 cell line, showing statistically significant reduction at concentrations ≥ 40 ug/mL and 10 ug/mL of GEM-CaP NPs in 48 and 72h of incubation, respectively, and IC50 at 160 ug/mL and 40 ug/mL of NPs in 48 and 72h of incubation, respectively. The present results are promising for future procedures in nanomedicine using GEM-CaP NPs.

Oral biofilms are structures that shelter different types of microorganisms. Biofilms are formed when planktonic microorganisms attach to teeth surface and buccal mucosa and start secreting an extracellular polymeric substance (EPS), composed of extracellular nucleic acids, proteins, and exopolysaccharides, which gives the structure a net negative charge. Oral biofilms can cause periodontal disease, endodontic infections, and dental caries, and are also related to systemic deceases, like cardiovascular disease, rheumatoid arthritis, and respiratory disease, according to some evidence. The biofilm matrix, consisting of EPS, has channels for transporting nutrients and water and protects the residents against the outer environment, immune system attacks, and antibiotic substances [1]. Therefore, the goal of this work is the synthesis and physicochemical characterization of polymeric micelles of the tri-block PEI-*b*-PEGMA-*b*-PCL aiming for the application in the treatment of oral biofilms. The polymer is synthesized in two stages, firstly via ring-opening polymerization of ε-caprolactone with PEGMA [2] as initiator and Tin (II) 2-ethylhexanoate ($Sn(Oct)_2$) as the catalyst and then functionalized with PEI by aza-Michael addition in mild conditions. 1H NMR and FTIR spectroscopies confirmed the formation as PEGMA-*b*-PCL, which presented an average ζ-potential 7.58 mV in a pH 4. The addition of PEI is expected to raise the positive surface charge, enabling greater electrostatic interaction between the nanoplatform and the biofilm.

e-mail: Izabel.amaral@icf.ufal.br

The main antimicrobial assets of today are silver nanoparticles (NPAg). Several methods ofsynthesis of silver nanoparticles are used, among them, biogenic synthesis, which consists ofthe use of biological materials as a reducing/stabilizing agent. The Alagoas red propolis(RPA), has several biological activities, such as: antibacterial, antifungal, antioxidant andanti-inflammatory, showing a promising biological agent in the synthesis of silvernanoparticles. Silver nanoparticles with red propolis from Alagoas (NPAg-RPA) wereobtained through biogenic synthesis and characterized by UV-Vis, DLS, Fluorimetry, PXRD,FT-IR and Raman techniques. By UV-Vis was observed band around 414nm, referring to theSPR band, inducing the formation of nanoparticles. Through the PXRD, peaks at angles 2θwere observed in 38.04, 44.80 and 64.54, which refer to the crystalline planes of metallicsilver. By the FTIR technique was observed an interaction of silver with red propolis, thedisplacements of bands observed indicate the participation of RPA in the reduction of silverand formation of NPAg-RPA. By Raman spectroscopy, bands close to carbonyl vibrations areobserved, indicating the participation of RPA in the stabilization of NPAg-RPA. The analysisof fluorimetry indicated a decrease in the fluorescence intensity of silver nanoparticle after theformation of NPAg-RPA, proving its achievement. The compound obtained in the presentwork represents a promising nanobiotechnological compound with antibacterial activity,especially for topical applications.

e-mail: livia.g.pacifico99@gmail.com

Hydroxyapatite (HA) is one of the most studied phase of the calcium orthophosphate family of compounds due to its excellent properties of biocompatibility, bioactivity, and controlled biodegradability [1]. HA nanoparticles (NPs) exhibit self-activated photoluminescence (PL) under UV-Vis irradiation, which can be used for distinct applications such as cellular imaging for the diagnosis of diseases including various types of cancer [2]. The PL property in HA NPs is mainly caused by the presence of a large density of point and structural defects, which can be tuned to modify the main characteristics of the emission band, such as intensity, emission color, lifetime and quantum yield [3]. This study aims to demonstrate the influence of carbon impurities on the luminescence of HA NPs synthesized by chemical precipitation followed by heat treatment at 400ºC/4h. Samples were initially characterizedvia X-ray diffraction (XRD), Fourier transform infrared spectroscopy (FTIR), Thermogravimetric analysis (TGA), and transmission electron microscopy (TEM). Then, PL spectroscopy revealed the impurities have profound impact on PL properties of HA including the intensity, color, and broadness of the emission band. Then, the cell viability of our HA NPs was probed via MTT assay, and their performance in cell imaging was tested via confocal microscopy, showing promising results for future bioimaging procedures in nanomedicine.

e-mail: luis.morato@unesp.br

Pesticides are chemicals used to protect the crops against intruders that can damage the plantation. However, their irregular use can lead to environmental contamination and, consequently, human intoxication. Furthermore, the mixture of two or more contaminants can favor the "cocktail effect", i.e., the combined effect of multiple products in the human health. Acephate is an insecticide from the organophosphorus family, can cause disorders in the human neurological system, and was the first pesticide found irregularly in Brazilian crops between 2017 and 2018. Diuron is an urea-class herbicide mainly used in sugarcane plantations and has carcinogenic potential in the bladder region. In order to investigate the combined effect of the acephate/diuron mixture on the bioinspired cell membrane model, Langmuir monolayers of POPC, cholesterol (Chol) and sphingomyelin (SM), and their mixture (ternary monolayer - 70/20/10 mol%, respectively) were explored in this study. The Langmuir monolayers were characterized by π-A isotherms and PM-IRRAS (Polarization Modulation-Infrared Reflection Adsorption Spectroscopy) in absence and presence of the acephate/diuron cocktail. A shift to higher molecular areas was observed to the π-A isotherms of POPC and ternary monolayers, while for Chol and SM no significant changes were noticed. A more detailed investigation was reached at intermolecular interaction by using PM-IRRAS, revealing that the pesticide mixture affects the polar head group of POPC, which is in agreement with molecular dynamics simulation. Acephate/diuron also affect the polarhead group of SM lipids and, additionally, the amide-I region. The intermolecular interaction between the pesticides with POPC and SM were also observed in the ternary lipid monolayer. This study finds evidences in the harmful effects of acephate and diuron in the lipid assembly that maintains the integrity of cell membranes.

Theranostic nanoparticles based on dual therapy: Proton Sponge and Nanorods against tumor normoxia and hypoxia conditions

Bianca Martins Estevao[1,2], Thales Rafael Machado[1], Celisnolia M. Leite[1], Nathalia Cristina Rissi[1], Valtencir Zucolotto[1]

e-mail: bianca_estevao@hotmail.com

Tumor hypoxia is increasingly recognized as an important detrimental factor in cancer therapy, compromising therapy and driving malignant progression [1]. Conventional chemotherapy is increasingly suffering from drug resistance in advanced stages of cancer, leading to trials and the use of new therapies [2,3]. Our study consisted in the application ofa dual therapy based on thermal and tamponade therapy, in the battle against pancreas (PANC-1) and lung (A549) cancerous cells. Traditional MCM41 and Periodic mesoporous organosilicas (PMOs) sensitive to pH were synthed as a shell around gold nanorods through the sol-gel method, obtaining stable nanoparticles of 180 - 230 nm with hexagonal pore ordering. A model drug for studying the buffer effect was TMGN (1,8(tetramethylguanidino)naphthalene), known as proton sponge, in which the encapsulation in the pores of the silica NP was about 30%. Photothermal experiments showed that despite the silica shell, the nanorods exhibited a temperature rise of 15°C after10 minutes of illumination with an 808 nm laser. Cell viability studies showed that the nanoparticles, when incorporated individually (laser off), had greater effects on hypoxic cells than those incubated under normoxia, in addition to the fact that MCM-41 has no toxicity. The toxic effect without laser application at 808 nm (hyperthermia) was associated with the proton sponge action. When the laser was activated, we observed a synergistic effect between the therapies (buffer and hyperthermia) in both cell lines, as well as an increase in drug delivery in the presence of the high temperature, leading to a new theranostic platform for anti-cancer application.

e-mail: euller.melo@icbs.ufal.br

Titanium dioxide (TiO2) nanocrystals (NCs) have wide industrial and pharmaceutical application. Due to its ability to absorb UV light and high refractive index, TiO2 is used in sunscreen, and in paints and foods as dyes. The applicability of TiO2 raises questions about its safety, both for the environment and for human health, since evidence indicates that TiO2 has cytotoxic, genotoxic effects and carcinogenic potential. Therefore, studies that determine the toxic effects of nanomaterials and methodologies, such as doping, that bring new properties to nanomaterials are essential. Thus, this work aimed to evaluate the toxicological effects of TiO2 NCs doped with Europium and 0.5 Calcium (TiO2:4Eu:05Ca) in *Drosophila melanogaster.*30 first instar larvae (n=6) were orally exposed to different concentrations of TiO2:4Eu:05Ca (0.5; 1.0; 2.0; 4.0 mg/ml) added to standard medium, and the effects during the development of the animals were analyzed. The larval and pupal lethality rates, the development time and the lifespan of the animals were quantified and showed no differences when compared to controls. Damage to the intestinal epithelium was measured using the trypan blue exclusion method. The results indicate that the NCs were biocompatible at the tested concentrations. However, further studies are needed to fully understand the mechanisms by which Calcium improved TiO2:4Eu:05Ca biocompatibility.

Understanding the interaction of acetogenin withcancer cell membrane models by DPPS Langmuirmonolayers

Matheus Elias Rosa[1], Ivanildo Afonso de Brito[2], João Henrique Ghilardi Lago[2], Luciano Caseli[3]

[1]Universidade Federal de São Paulo, [2]Universidade Federal do ABC, [3]Universidade Federalde São Paulo (*Department of Chemistry*)

e-mail: maths_elias@hotmail.com

Acetogenins are a class of biomolecules derived from Annonaceae family plants which recently has shown cytotoxic properties, along with antitumor and antiparasitic activity. However, as its biological activities are widely studied, its molecular mechanism of action is not yet known. As a result, it is crucial to understand if the drug acts by provoking alterations in the physical-chemical properties of the cell membranes or if it penetrates the membrane and acts on intracellular structures. It is also relevant to study the interaction of such kind of bioactive molecules with phospholipids to develop possible drug carrier systems, such as liposomes. To fill these gaps, we studied the action of an unsaturated acetogenin named PMD3, extracted from Porcelia macrocarpa seeds, in cell membrane models at the air-water interface by Langmuir monolayers composed of the phospholipid dipalmitoylglycerophosphoserine (DPPS), since phosphatidylserines, predominant lipids in the inner leaflet of the plasma membrane, are encountered at high concentrations in the outer leaflet of tumor cell membranes. The characterizations of pure DPPS and mixed (DPPS + PMD3) films were made by surface pressure-area isotherms, hysteresis and tensiometric stability assays, polarization modulation infrared reflection absorption spectroscopy (PM-IRRAS) and Brewster angle microscopy (BAM). The introduction of the drug on the lipid monolayer caused a higher orientational disorder, lower stability, and other alterations in the physical-chemical properties of the film. PM-IRRAS spectra show that PMD3 interacts on both the alkylic and polar portions of DPPS. These results may be related to the mechanism of PMD3 on tumor cell membranes and should be fundamental to better selecting tumorigenic drugs as bioactive materials.

Unveiling the Ultrastructure of Microbial Cell Walls: Investigating the Effects of AIP6 Cell-Penetrating Peptide Using Atomic Force Microscopy

Louíse Eloá Araújo Souza[1], Emerson Rodrigo da Silva[2]

[1]Universidade Federal de São Paulo (*Biofísica*) , [2]Universidade Federal de São Paulo(*Biofísica*)

e-mail: louise.eloa@unifesp.br

The pentapeptide RLRWR (AIP6) belongs to the group of cell-penetrating peptides (CPPs), being one of the shortest sequences capable of translocating biomembranes. While the interaction of CPPs with mammalian cells has been extensively investigated, studies on the effects of these molecules on the cell wall of microorganisms have not been carried out at the same intensity. Herein, we investigated the interaction of the AIP6 peptide with the cell wall of model microorganisms using Atomic Force Microscopy (AFM) techniques capable of providing ultra-high resolution and detailed physicochemical data. We developed analysis protocols that allowed us to obtain three-dimensional details of these interfaces, both in fixed samples and living cells maintained under hydrated conditions. We also characterizedthe spectroscopic signature of the cell wall at the nanoscale. The model organisms investigated in this study were the procaryotic E. coli and B. subtilis, whereas the eukaryotic model was the yeast S. cerevisae. Topography AFM data and nano-spectroscopy (AFM-IR) experiments were performed on PFA-fixed slides containing cells previously incubated with AIP6. Live cell imaging was conducted using BioAFM with culture medium-containing cells adhered to polylysine-treated glass slides. MICs were found in the range of 0.1-1mg/ml, and AIP6 was found to be selective to the Gram-positive B. subtilis. Ultrastructural analysis of the cell wall allowed the observation of pores, and the formation of peptide domains was identified through the spectroscopic signature. The AIP6 peptide showed affinity for the cell walls of bacteria, especially B. subtilis, while no action was observed against S. cerevisiae. In prokaryotes, the formation of peptide domains that likely induce the formation of pores responsible for cell lysis was observed.

e-mail: priscila.alessio@unesp.br

The investigation of the impacts of emerging pollutants on cellular systems is crucial for comprehending their potential risks to human health and the environment and developing effective strategies for their mitigation. Some emerging pollutants, such as BPA, some pesticides, and hormones have some of their effects known. However, the toxicity of emerging pollutants in mixtures can generate effects that are different from those observed when each individual compound is evaluated separately. These combined effects of water contaminant mixtures may be additive, synergistic, or agonistic. This work discusses the issue of emerging pollutants and their potentially harmful effects on human health and the environment, with a particular focus on two types of pollutants: antibiotics (amoxicillin) and dyes (methylene blue). The study examines the effects of these pollutants and their mixture on cell membrane models based on lipid monolayers and bilayers. Using Langmuir films, the study revealed a synergistic effect for the mixture of pollutants on lipid monolayers through π-A isotherms and PM-IRRAS spectroscopy. In contrast, the bilayer systems from giant unilamellar vesicles (GUVs) and contrast phase microscopy experiments suggested similar molecular effects for individual pollutants and the mixture, with a predominance of the MB effects. The study considered the critical factors of chemical interactions and molecule for their different effects on the cell models. This research emphas the importance of comprehending the molecular impacts of emerging pollutants on human health and developing models to investigate their interactions with the cell membrane.

Zein-propolis Electrospun nanofibers: a potent antimelanoma material

Anderson Fraga da Cruz[1], Sabrina Hochheim[2], Izabel Cristina Riegel-Vidotti[3], Carolina Camargo de Oliveira[1]

[1]Universidade Federal do Paraná (*Biologia Celular*) , [2]Centro Universitário Leonardo da Vinci,
[3]Universidade Federal do Paraná (*Química*)

e-mail: andersonfraga@ufpr.br

Propolis is a natural resinous substance produced by bees, which have many biomedical properties, such as antitumor and immunomodulatory activity[1]. The main problem using it as a therapeutical agent is its high hydrophobicity. Using zein, the main protein in corn with over 50% of its amino acids present an apolar character easing hydrophobic interactions[2], to electrospun nanofiber formation, propolis can be controlled released in biological environment. Considering this, we prepared thermally annealed zein-Propolis electrospun nanofibers with no or 45mg/mL of propolis, that already showed no cytotoxic effects in non-tumoral skin cell line [3]. After nanofiber preparation, human melanoma and melanocyte cell lines (A375 and NGM cell lines, respectively) were plated over nanofibers. Cells were allowed to interact with nanofibers for 72 h. After, cell viability was measured by neutral red uptake. Results showed reduction in melanoma cell viability and increase of neutral red uptake from melanocyte cell line, indicating that the nanofiber can be used as a delivery platform for propolis to cells and that melanoma cell viability are more affected than non-tumoral cells. Further experiments need to be performed using other cell lines to determinate this specific activity, and evaluating why there is difference between the tumoral and non-tumoral cell lines. In conclusion, thermally annealed zein-Propolis electrospun nanofibers, a natural biocompatible material, appears to be a potent material with specific cytotoxic activity on human melanoma cells while enhancing non-tumor cell proliferation.

G-Photocatalytic materials applied in energy conversion and environmental remediation

How Photocatalytic Materials can contribute for a Sustainable Agriculture

Caue Ribeiro de Oliveira[1]

[1]EMBRAPA Instrumentação (*P&D*)*e-*

mail: caue.ribeiro@embrapa.br

The literature about application of photocatalytic materials is continuously introducing new promising catalysts, but the context of applications is still far from consistent scenarios, based on actual demands. In particular, agriculture can be benefited by these technologies if they can attend specific challenges, which frequently requires robustness and adequacy to be applied to extremely high scales. Thus, the understanding of the boundary conditions can helps to the development of feasible solutions based in the current knowledge. Here we propose to revise several applications, from the literature and of our research group, where photocatalytic materials are playing a role – as CO2 reduction, CH4 reforming, NO3 and N2o oxidation, among others. A revision about the efforts on the more consolidated applications (e.g. photdegradation of agrichrmicals in water) to those still in infancy (e.g. N2 reduction) can give a good portfolio for materials scientists to contribute to a sustainable agriculture.

Misfit Ca-cobaltites as promising electrodes for fuelcells and electrolyzers

Daniel Macedo[1]

[1]Federal University of Paraíba (*Engengaria de Materiais*)

e-mail: damaced@gmail.com

This lecture focuses on the review the recent efforts of the Materials and Electrochemistry Interdisciplinary Group of the Federal University of Paraíba (GIME-UFPB) on the development of misfit calcium cobaltites (Ca3Co4O9, C349). These materials have emerged as promising functional electrodes for oxygen reduction and oxygen evolution reactions. The effects of Cu-doping and PrOx addition on the electrochemical activity of C349-based electrodes have been evaluated under typical operational conditions of solid oxide fuel cells (SOFCs) and alkaline electrolyzers. Powders obtained by a proteic sol-gel method and by solid state reaction, using mollusk shell as a natural source of calcium carbonate, have been systematically studied using a variety of characterization techniques. Electrodes were electrochemically characterized by impedance spectroscopy as a function of the temperature and oxgyen partial pressure. The electrochemical assessment indicated the materials developed at GIME-UFPB are very competitive in comparison to those from literature, highlighting the high potential of Ca-cobaltites for energy conversion applications.

Photocatalytic Reduction of CO2 using hybrid carbon-based materials

Conchi O Ania[1], Alicia Gomis Berenguer[2], Elhassan AMATERZ[1]

[1]Centre national de la recherche scientifique (*CEMHTI*) , [2]Universidad de Alicante (*Inst. Electroquimica*)

e-mail: conchi.ania@cnrs-orleans.fr

Replacing metallic catalysts with metal-free abundant materials has become a priority to boost sustainable and renewable solutions towards current energetic and environmental challenges. Many different forms of carbon have shown high catalytic activities, with better performance and durability than certain state-of-the-art non-precious metal catalysts for energy conversion/storage and environmental remediation. Among them, nanoporous carbons have attracted the attention since the outstanding role of nanopore confinement has led to reporting high photochemical quantum yields in a high number of oxidation and reduction reactions due to light activation of optically active sites. The stabilization of the photogenerated excitons in the nanopores facilitates molecular transformations of interest, such as the conversion of CO_2into fuels and added-value chemicals. In this study we have explored the use of nanoporous carbons with controlled pore architectures as photoelectrocatalysts for the reduction of CO_2, using supported electrodes (e.g., glassy carbon, titanium foil) and a cell provided with a quartz window and various irradiation sources (simulated solar light, LEDs). Some carbon materials showed a high conversion of CO_2into CO with a high selectivity for CO over H_2. Such selectivity correlates well with the electrochemically active surface area of the materials and it was higher for selected carbons doped with heteroatoms, due to the presence of surface defects upon functionalization. The studied carbons also displayed a good stability after several hours of reaction, as seen in the post-mortem analysis of the catalysts. We herein provide a comprehensive interpretation of the origin, reactivity and stabilization pathways of the charge carriers, with perspectives of utilization in photoelectrocatalytic reactors.

Shining a Light on Sustainable Chemistry: Harnessingthe Power of Photoelectrocatalysis for Clean Energy Conversion and Environmental Remediation

Dr. Andrea Folli[1]

[1]Cardiff University (*Cardiff Catalysis Institute - School of Chemistry*)

e-mail: follia@cardiff.ac.uk

Photoelectrocatalysis has emerged as a promising approach to address global challenges in energy conversion and environmental remediation, owing to its ability to simultaneously harness solar energy, facilitate charge transfer, and catalyse chemical reactions. The use of light as an energy source and electron transfer mediator enables the development of efficient and selective reactions that can convert solar energy into useful fuels or degrade harmful pollutants. The ability to convert solar energy into clean fuels, such as hydrogen, has the potential to transform the energy landscape and reduce dependence on fossil fuels. Furthermore, the use of photoelectrocatalysis for environmental remediation, such as the degradation of organic pollutants or nitrogen fixation for fertilizer production, can contribute to mitigating climate change and improving human health.

In this lecture, I will explore our research into earth-abundant and low-cost metal oxides for hydrogen evolution, biomass conversion, and air pollutants (such as NOx) abatement [1]; as well as carbon-based nanomaterials for de-halogenation and organics conversion [2]. For all these materials, I will show how combinations of electrochemical and magnetic resonance techniques afford a better understanding of the underlying mechanisms of photoelectrocatalytic processes, opening up exciting new avenues in sustainable chemistry for energy and the environment.

By continuously pushing the frontiers of what is achievable by converting solar energy efficiently, photoelectrocatalysis exemplifies the importance of interdisciplinary collaborations and creative thinking in tackling some of the world''s most pressing challenges.

Application of carbon fiber (CF/WO_3) used as photoactivated filtration membrane for sertraline removal

Hernán Dario Rojas Mantilla[1], Kallyni Irikura[1], João Carlos de Souza[1], Saidy Cristina Ayala Durán[1], Ricardo Andrés Salazar González[2], Maria Valnice Boldrin Zanoni[1]

[1]Universidade Estadual Paulista (*Institute of Chemistry, National Institute for Alternative Technologies of Detection, Toxicological Evaluation and Removal of Micropollutants and Radioactives (INCT-DATREM)*) , [2]Universidad de Santiago de Chile (*Facultad de Química y Biología*)

e-mail: hernan.mantilla@unesp.br

The application of photoactivated filtration membranes results in a promising alternative in the treatment of contaminated water since they allow the simultaneous retention/removal of emerging contaminants and minimize problems associated with filtration such as incrustation, deformation, continuous maintenance and less reusability. The present work proposes the hybridization of the filtration/photocatalysis systems, from the use of carbon fibers (CF) modified with n-type semiconductor (WO_3), via electrodeposition and heat treatment at 450 °C/2h, applied in the removal of Sertraline (SER); an antidepressant of extended use and with potential contaminant of water environments. Thermogravimetric analysis showed decomposition of C above 750 °C, proving the stability of CF for its modification by heat treatment. The micrographs showed uniform WO_3 deposition on the CF surface. The X-ray diffraction patterns showed characteristic peaks for (C and WO_3) and the presence of the monoclinic phase (high photoactive). The XPS analysis showed an asymmetrical peak of greater intensity at 530.3 eV, attributed to metallic bonding (W-O), and the presence of double symmetrical peaks at 35.3, 37.6 eV and 41.3 eV attributed to levels W $4f_{7/2}$, W $4f_{5/2}$ and W $5p_{3/2}$. The modified CF showed broad UV-Vis absorption (300 to 700 nm) and bandgap energy (E_g) 3.2 eV, as well as an increase in BET area from 0.2045 ± 0.0091 to 3.0826 ± 0.0224 m^2/g after WO_3 deposition with pore size between 13 and 33 nm characteristic of mesoporous materials. The filtration membranes showed high efficiency reaching complete removal of SER [1 mg L^{-1}] in 90 and 30 min when evaluated in Milli-Q water and in real effluent, as well as 66% degradation after 5 reuse cycles. The use of scavenger agents determined the fundamental role of hydroxyl radicals ($HO^{\cdot}$) and superoxide ($O_2^{\cdot-}$) in the SER degradation mechanism.

Bactericidal and virucidal activity of polymer-basedcopper coating boosted by visible light radiation

Aline Lucchesi Schio[1], Michele Strey de Lima[1], Rafael Dorighello Cadamuro[2], Alexandre Fassini Michels[1], Mariana Roesch Ely[1], Gislaine Fongaro[2], Carlos Alejandro Figueroa[1]

[1]Universidade de Caxias do Sul, [2]Universidade Federal de Santa Catarina

e-mail: alschio1@ucs.br

Before the pandemic caused by the severe acute respiratory syndrome coronavirus 2 which caused the death of more than 6.5 million people worldwide, the research of virucidal materials has been encouraged [1]. However, besides viruses, bacteria also represent a threat to human health as they are commonly responsible for nosocomial infections that exhibit a significant mortality rate. Among the materials studied, copper stands out due to its intrinsic biocidal properties [2]. The present work developed composite films containing different copper particles into a polyvinyl alcohol matrix. By applying the films with copper micro- and nanoparticles, *Staphylococcus aureus*population was reduced above 6 log orders after 4 h of incubation in the absence of light and under light illumination. The films with copper(I) oxide presented the same result only under visible radiation, proving that under illumination the material induces a quicker cell death. *Escherichia coli*showed more resistance, since in 4 h only the films with copper nanoparticles presented bactericidal activity. The films containing copper microparticles were tested against murine hepatitis virus, and 99.99% of the virus was inactivated after 30 min of contact. Thus, the composite films are an encourage strategy to combat any infection that can be contracted by common touching surfaces.

Bactericidal photocatalyst of TiO_2-based copper under visible light radiation

Michele Strey de Lima[1], Aline Lucchesi Schio[1], Rafaele Frassini[1], Mariana Roesch Ely[1], Cesar Aguzzoli[1], Carlos Alejandro Figueroa[1], Alexandre Fassini Michels[1]

[1]Universidade de Caxias do Sul

e-mail: mslima3@ucs.br

In recent decades, there has been growing interest in developing photocatalytic materials to address environmental and health-related issues. Following the SARS-CoV-2 pandemic, many researchers have focused on developing materials with bactericidal and virucidal properties that can be used as coatings in hospitals, public transportation and other institutions, to minimized the spread of infectious diseases. In this context, it is important to have a suitable photocatalyst with antimicrobial activity in the presence of visible light irradiation. TiO_2semiconductor and copper can be coupled to obtain a material with these desired properties [1][2]. In this study, we developed a new photocatalytic material through the heterojunction of commercial TiO_2nanoparticles with copper deposited by magnetron sputtering technique in distinct deposition times. Samples were characterized by Scanning Electron Microscopy, X-ray Diffraction, Raman Spectroscopy, Uv-vis Spectroscopy and Inductively Coupled Plasma/Optical Emission Spectrometry. To evaluate photocatalytic activity, degradation of Rhodamine B dye was quantified in presence of the samples, under irradiaton at 405 nm. Bactericidal activity was assayed with *Escherichia coli*at 405 nm and in dark conditions to obtain minimum inhibitory concentration (MIC) of tested samples. The characterization confirmed presence of anatase as major phase and copper in low concentration (< 5,0 % w/v). The degradation of Rhodamine B dye was effective under visible light conditions, as well as the bactericidal activity, with a MIC of 12,5 $mg.L^{-1}$for the sample with 30 minutes of copper deposition. The plasmonic nanostructures obtained will be further evaluated for virucidal activity and other light conditions.

The conversion of CO2 into fuels or chemical raw materials can be part of the solution to environmental and energy crises. The photocatalytic reduction of CO2 pollutant to substances of higher aggregated value can already be observed in a variety of studies. However, for this process to become viable, the development of catalysts that present high selectivity, long-term stability, and low overpotential is crucial. [1] In this context, CuO is a promising material that can convert CO2 into both alcohol and hydrocarbons. In this work, we studied the influence of adding different bases during the synthesis of CuO catalyst by the chemical precipitation route [2]. The studied bases were NaOH, KOH, monoethanolamine (MEA), and NH4OH. We selected MEA as a base with the aim of creating a surface functionalization on CuO catalyst, which can act as CO2 adducts andimprove the catalyst efficiency during photo or electroreduction processes. The synthesizedcatalysts were characterized via X-ray Diffractometry (XRD) and X-ray Photoelectron Spectroscopy (XPS), proving the CuO phase as the crystalline structure of all the samplesand the presence of nitrogen in the CuO/MEA catalyst surface. The use of different bases onthe synthesis of CuO by precipitation route has shown great influence in its photoactivity forCO2 reduction. The CuO/KOH and CuO/MEA samples presented enhanced gaseous production in comparison with samples CuO/NH4OH and CuO/NaOH. The CuO/MEA sample achieved the best photoactivity and selectivity, which was attributed to the surface functionalization by nitrogen groups.

The growing world population and industrial development have caused concerns regarding energy crises and environmental damage. Solar energy and photocatalytic technology using semiconductor materials such as ZnO, TiO2, and NiO are promising solutions for the degradation and inactivation of chemical pollutants, and are clean, safe, and effective [1]. Nickel oxide (NiO), one of the most widely used transition metal oxides, has a wide band gap (3.0 - 4.0 eV) and can be synthed using cost-effective methods, such as solution combustion synthesis (SCS) [2]. SCS is a versatile method in which metal salts, water, and organic fuel are mixed and ignited by heat, resulting in oxide or metal nanoparticles (NPs). It is well known that the characteristics of the final product are strongly dependent on the amount of heat generated and gases released during the combustion reaction [3]. In this study, a nanocrystalline NiO photocatalyst was synthed by the SCS method using nickel nitrate as the oxidizer and sucrose as the fuel, by varying the fuel-to-oxidizer ratio (Φ) from fuel-leanto fuel-rich in a muffle furnace preheated at 500 °C. The effect of Φ on the SCS mechanism, morphology, crystallinity, surface area, and optical properties was investigated by SEM, XRD, BET/BJH, and UV-Vis spectroscopy. The photocatalytic activity was evaluated undervisible light using TC-HCL as the pollutant model. NPs synthed under fuel-rich conditions exhibited metallic Ni in addition to NiO. Under fuel-lean conditions, only NiO was observed,and the particles presented a higher surface area, resulting in better photocatalytic activity.

e-mail: mariaeduarda.silva@cetene.gov.br

Green hydrogen is the focus of current research on renewable and sustainable fuels. For water splitting, TiO_2photoanodes (Eg^{bulk}= 3.2 eV) dedicated for oxygen generation are limited by the narrow solar radiation absorption window. Thereby, sensitization with CdTe quantum dots is of great interest due to the easy adjustment of the optical band gap and consequently the relative positioning of bands, largely controlled by the nanoparticle . Thus, the current work is dedicated to the study of energy transfer mechanisms at the interfaces of TiO_2/CdTe semiconductors as a function of the relative positioning of bands of the two semiconductors. TiO_2nanotubes supported on Ti foils were produced by sonoelectrochemical strategy.[1] The CdTe quantum dots stabilized by 3-mercaptopropionic acid (MPA) were produced via electrochemistry, from the in situ reduction of Te^0.[2] The control of CdTe was done through different heating times leading to tuning from green (λ_{em}= 529 nm, Eg = 2.40 eV) to red (λ_{em}= 643 nm, Eg = 1.98 eV). The system has a higher luminescence quantum yield (QY) for yellow nanoparticles (24.96%). The best sensitization times of TiO_2NTs and CdTe-MPA were evaluated using electrochemical techniques such as chronoamperometry, linear voltammetry and electrochemical impedance spectroscopy. The results indicated that6 hours is the best sensitization time of TiO_2, and the heterojunction made by TiO_2/CdTe. The best electrocatalysis performance was for yellow CdTe, presenting photocurrent densityof 1.80 mA/cm^2, showing an increase of 9x in relation with pure TiO_2. The obtained results demonstrate the material potential to application in hydrogen production.

Light-driving photoconversion of CO2 into Solar Fuels

Yong Zhou[1], Congping Wu[2], Zhigang Zou[2]

[1]Anhui Polytechnic University, [2]Nanjing University

e-mail: zhouyong1999@nju.edu.cn

In recent years, the increase of carbon dioxide (CO2) in the atmosphere has become a global environmental issue because of the serious problems, such as the “greenhouse effect”. The idea of mimicking the overall natural photosynthetic cycle of chemical conversion of CO2 into useful fuels has been consistently gaining attention for more than thirty years. Such artificial photosynthesis allows direct conversion of CO2 and water on photocatalysts into valuable hydrocarbon using sunlight at room temperature and ambient pressure to serve to reduce atmospheric CO2 concentrations while providing on a renewable carbon fixation and energy storage. In this presentation, we will report the utilization of solar energy to highly efficient conversion of CO2 into renewable hydrocarbon fuel over structured nanomaterials. The geometric shape and exposure of specific crystal planes of the nanostructures proves a requisite for the high level of photocatalytic reduction of CO2 and formation of C2+ species.

e-mail: pinheiro.thais@ufabc.edu.br

The advantages of Titanium Dioxide (TiO_2) in nanobiotechnology are its non-toxicity, availability, cost-effectiveness, wide bandgap semiconductor, good biocompatibility, stability, and physical and chemical properties. TiO_2nanotube arrays are particularly useful for photocatalysis processes for pollutant degradation, H_2generation, and self-cleaning properties. However, TiO_2has a restricted photocatalytic efficiency due to its wide bandgap (3.2 eV), which limits the amount of solar radiation it can efficiently absorb in 4-7%. To improve the efficiency of TiO_2, researchers have explored several methods, including the addition of graphene oxide (GO) as a co-adsorbent. The GO has a high specific surface area and strong light absorption property that can improve the photocatalytic efficiency of TiO_2, but it also contains a large number of oxygen-containing functional groups that reduce its electronic properties. Therefore, researchers need to modify the GO to reduced graphene oxide (rGO) to recover its charge carrier mobility and reduce the number of oxygen-containing functional groups. Hence by these facts, this research investigates the performance of TiO_2/rGO NTs in photocatalytic degradation of the methylene blue, as well as the properties of the produced GO and the various heterostructures of TiO_2/rGO NTs, produced by a low-cost thermal reduction at a different range of temperatures (400/420/450/470/500/520°C) for 2 and 5 hours, using various analysis techniques, such asUV-Vis spectroscopy, XDR, Raman, FTIR, SEM, TGA, DTG, DSC, and zeta potential analysis.

Magnetic activated carbon for improving the removal of antibiotics from water by heterogeneous solar photo-Fenton

Karla Virginia Leite Lima[1], Erika Maria Leite de Sousa[2], Diana Luísa Duarte de Lima[2], Vânia Maria Amaro Calisto[2], Raquel Fernandes Pupo Nogueira[1]

e-mail: k.lima@unesp.br

Activated carbon (AC) has been considered as a promising support for Fe-based solid catalysts in heterogeneous Fenton oxidation, due to its low cost and environmentally friendly properties [1]. However, few studies have investigated the application of AC-derived catalysts in photo-Fenton for pharmaceutical removal. Therefore, this study aimed to develop a magnetic activated carbon-based catalyst (MAC-Fe) and evaluate its efficacy in removing antibiotics sulfamethoxazole (SMX) and trimethoprim (TMP) from water. The MAC-Fe catalyst was produced by impregnating KOH and $FeCl_3$in one step, a simplified and potentially cost-reducing process that combined the chemical activation and magnetization into a single step. The determination of pore morphology and specific surface area (SBET) showed that MAC-Fe has a suitable microporous structure (~16% micropore volume) and reasonable SBET (41 $m^2 g^{-1}$). Also, high saturation magnetization (Ms) of 21.14 emu g^{-1}exceeds most reported magnetic-activated carbons [2]. To evaluate the real contribution of MAC-Fe in the removal of antibiotics, the ability to remove SMX and TMP were studied with 250 mL of a mixed solution containing 200 μg $L^{-1}$of SMX and TMP, MAC-Fe 0.25 g L^{-1}, $H_2O_2$5 mM at pH 8.0. The results of MAC-Fe application for antibiotic removal suggested that the photo-Fenton and Fenton-heterogeneous processes were the most effective in eliminating the antibiotics, followed by adsorption. In the whole removal process, adsorption can serve as the initial step, whereby the MAC-Fe adsorbs antibiotics and H_2O_2onto its surface. Overall, this study suggests that using MAC/Fe in heterogeneous photo-Fenton processes is an effective strategy for removing SMX and TMP from water.

Semiconductor nanoparticles can be made available by solution combustion synthesis (SCS), a cheap, simple, scalable and very fast method that has been used for a wide range of applications [1]. This method, conventionally carried out in muffle furnaces, has been modified so that the reaction is initiated by microwave irradiation, called Microwave Assisted Solution Combustion Synthesis (MASCS) [2]. Such a modification resulted in much faster heating and cooling rates compared to conventional SCS, thereby increasing the number of defects on the nanoparticle surface, narrowing the band gap, reducing the particle size and increasing the porosity of the synthesis product. Unlike previous reports in the literature [1-3], this work used a mixture of fuels (sucrose and urea in a molar ratio of 1:1) in solution to achieve a one-step synthesis and doping of the ZnO nanoparticles. The doping effect - confirmed by XPS, XRD and UV-Vis spectroscopy - greatly improved the ability of the developed material to remove tetracycline from water under visible light photocatalytic assays, where the doped materials showed over 90% pollutant removal in 120 minutes.

Research using semiconductors as photocatalysts has been carried out since the 70s. In this photocatalytic process, photons with energy equal to or greater than the band gap energy absorbed by the semiconductor, generate electron/hole pairs, thus creating oxidizing and reducing sites in its surface. Many factors affect the activity of photocatalysts such as particle size and optical absorption capacity. Sodium niobate (NaNbO3) is a promising photocatalyst however, the natural shape of particles are large cubes, but research has already reported nanoparti-cles with high photocatalytic activity [1]. In addition, it only absorbs ultraviolet light, limiting its use. Therefore, it is highly desirable to extend the optical absorp-tion into the visible range. Eumelanin is a pigment present in abundance in fau-na and flora, responsible for the black-brown color. It has many physicochemical properties, of particular interest here broad optical absorption ranging from UV to near infrared and strong affinity by metals [2]. Given the above, we present a rapid method to synthesize NaNbO3 nanoparticles. These nanoparticles were used to prepare for the first time a NaNbO3/Eumelanin composite with photocatalytic ac-tivity under visible light. The photocatalytic activity was analyzed through the deg-radation of Rhodamine B (RhB), a dye widely used in industry and highly toxic. The results showed that pure NaNbO3 and pure Eumelanin do not show photo-catalytic activity, while the composite was able to successfully degrade the dye. Therefore, this study presents an alternative photocatalyst that uses visible light and widely available elements, serving as inspiration for the development of new photocatalysts.Acknowledgements: CAPES, CNPq, FAPERGS, UNIFESP Campus São José dos Campos e UNIPAMPA Campus Bagé.References:[1] D. This work presents a study on the optimization of materials for use in photocatalysis and solar energy conversion. Niobium-based materials such as Nb2O5, NaNbO3, and KNbO3 have been shown to improve the efficiency of these devices. In this study, we have used Density Functional Theory (DFT) calculations to determine the most suitable dopants to reduce the bandgap and enhance the performance of these materials. The optimized materials have been obtained through theoretical and experimental studies. Our results demonstrate the significant improvement in the efficiency of these devices with the optimized niobium-based materials. This research contributes to the development of more efficient materials for use in renewable energy applications, such as solar cells and photocatalysts.

Optimizing sucrose-urea fuel mixture in solution combustion synthesis of N-doped zinc oxide nanoparticles for enhanced photocatalytic removal of tetracycline hydrochloride

e-mail: taina.pigosso@labmat.ufsc.br

Recent data have revealed the detection of approximately 160 emerging contaminants in Brazil and 60 in different regions of the world, which can cause adverse or lethal problems [1]. Semiconductor-based photocatalysis is a green technology for the environmental remediation of these substances. Zinc oxide (ZnO) has been applied as a photocatalyst with proven activity for pollutant abatement [2]. This research aims to design and manufacture nitrogen-doped zinc oxide nanoparticles using a one-step approach by tailoring the molar ratio of urea-to-sucrose as fuels in a mixture with zinc nitrate hexahydrate as the zinc precursor. Five samples were prepared to vary the molar ratio in fractions of 0%, 25%, 50%, 75%, and 100% of urea, in a heated Muffle furnace at 500 ºC for 10 min. Physicochemical properties of the N-doped ZnO were investigated through XRD, SEM, DLS, BET/BJH, XPS, and UV/vis. Photocatalytic removal of the model emerging pollutant tetracycline hydrochloride (TC - HCl) was performed under light (15 W, λ >420 nm) with the N-ZnO as photocatalysts. The results reveal the feasibility of producing one gram of ZnO in a short time. Nano-ZnO with a urea-to-sucrose molar ratio of 50% had a surface area of 26 m^2/g, mesoporosity, and a band gap of 2.89 eV. These features enhance the photocatalytic removal of the TC - HCl to around 75% for 60 min of irradiation, which means an efficiency improvement of 40% and a removal rate 1.86 faster than the ZnO undoped. After 120 min, the photocatalytic degradation of TC - HCl is almost 100% due to the synergy of material's porous structure and a narrow band gap.Keywords: N-doped zinc oxide; solution combustion synthesi photocatalysi visible light active.

Green hydrogen emerges as a great candidate for obtaining clean and renewable energy and its photoelectrochemical production is one of the frontiers of research. Titanium dioxide (TiO_2) stands out compared to other semiconductors due to its stability[1]. However, its bandgap (Eg = 3.2 eV) does not allow absorption of the entire solar spectrum. Thus, heterojunctions that allow increased radiation absorption and efficient transfer are of research interest. Copper spinels and bismuth $CuBi_2O_4$(CBO) can act as a TiO_2sensitizer for photoelectrochemical conversion of solar radiation to green hydrogen, given its significant spectral absorption region and positive flat band[2]. The present work was dedicated to the electrodeposition of BOD on the nanostructured surface of $TiO_2$and the characterization of the photoelectrochemical performance of photoanodes prepared for OER. From supported TiO_2nanotubes, $Cu^{2+}$and Bi^{3+}ions were deposited, evaluating the effect of electrical chargeson chronopotentiometric processes and ion concentration (in dilution factors of 50-100x).After electrodeposition, the BOD samples were dried and thermally treated at 500◦C. The materials produced were structurally characterized by X-ray diffraction, verifying the formation of the crystalline phases of interest for spinel BOD and TiO2. Scanned electronmicroscopy images showed the evolution of surface micro- and nanostructures. The photoelectrochemical characterizations allowed access to the electrochemical performance data of the produced photoanodes. Based on the experimental design (load x concentration), the best condition can be determined leading to a photocurrent density of around $1mA/cm^2$, under simulated solar irradiation (filter AM1.5G, 100 mW. cm^{-2}, S^{2-}/SO_3^{2-}, pH 13) a 4x performance increase over pure TiO_2.

e-mail: tommaso@puc-rio.br

The CO_2reduction reaction is up today exploited for the synthesis of value-added feed-stocks in gaseous or liquid form [1]. Here we report an example of CO_2reduction reaction leading to the production of advanced functional nanomaterial by the use of pulsed laser ablation ofa gold target in water. The presence of CO_2derivatives in water during the ablation process, leads to C2 and C3 coupling with the production of organic material with the typical fingerprint of the CO_2reduction reaction. Carbon monoxide rich gold nanoparticles and metal-organic nano-frameworks composed by gold nanoclusters and carboxylic acid crystals, are produced by the catalytic reactions induced during pulsed laser ablation, together with metal-free carboxylic acids and residual carbon nanomaterial in tubular and onion like structure. Using a novel pump and probe configuration for the pulsed laser driven CO_2reduction reaction, we are able to obtain ultra-small AuNPs (d < 3 nm) and photoluminescent metal-organic nano-framework with a quantum-yield of the about 23% in the blue spectral region [2]. The authors acknowledge CAPES, CNPq and FAPERJ for the support.

Removing antibiotics from water via solar photo-Fenton using cobalt containing magnetite

Jany Hellen Ferreira de Jesus[1], Karla Virginia Leite Lima[2], Raquel Fernandes Pupo Nogueira[3]

[1]Universidade Estadual Paulista / Instituto de Química (*Dep de Química Analítica, Inorgânica e Físico-química*) , [2]Universidade Estadual Paulista (*Química Analítica, Físico-Química e Inorgânica*) , [3]Universidade Estadual Paulista / Instituto de Química

e-mail: jesusjanyhf@gmail.com

Fenton-type reactions are effective for the generation of hydroxyl radicals which can degrade contaminants in wastewater. Magnetite contains Fe(II) and Fe(III) species that areimportant in the catalytic activity of the Fenton reaction. Furthermore, the iron in the magnetite structure can be replaced by other metals, such as cobalt, improving the catalyticproperties of the material [1]. In this work, the influence of cobalt on magnetite structuretowards the Fenton process was studied, where $Fe^{2+}$was replaced by Co^{2+}in previously chosen stoichiometric. The photo-Fenton experiments were conducted under solar irradiation, from 11:00 am to 1:00 pm, in an open glass reactor with a maximum capacity of 300 mL. The catalytic activity of magnetites was evaluated based on the degradation of sulfamethoxazole and trimethoprim. Although cobalt ions incorporation on magnetite structure showed no significant difference on degradation after 90 min in the dark, complete degradation of both antibiotics was achieved after 45 min under solar irradiation (86 kJ m^{-2}accumulated UVA dose) using $[Co_{0.25}Fe_{0.75}][Fe_2]O_4$, the most efficient catalyst. Unexpectedly, $[Co_{0.25}Fe_{0.75}][Fe_2]O_4$was the magnetite with the lowest specific area (144 m^2g^{-1}). Cobalt exhibit the redox pair Co^{2+}/Co^{3+}, which can produce radicals according to the reaction $Co^{2+}+H_2O_2\rightarrow Co^{3+}+OH^-+{}^{\cdot}OH$. Also, the reduction of $Co^{3+}$by $Fe^{2+}$is thermodynamically favorable ($Fe^{2+}+Co^{3+}\rightarrow Fe^{3+}+Co^{2+}$, $\Delta E=1.04$ V), by an electron transfer process within the oxide structure [1]. This finding indicate that the higher catalytic activity of $[Co_{0.25}Fe_{0.75}][Fe_2]O_4$can be attributed to the cobalt incorporation, which plays a more important role in the photo-Fenton processes than the specific area of the catalyst under the conditions applied.

e-mail: jose.pacheco@ufpe.br

The water shortage crisis has pressured industries to adopt water reuse practices. Self-cleaning membranes are a promising solution for effluent treatment, followed by the regeneration of the used membrane clogged with contaminants. In this work, a prepared cellulose-MIL88A membrane presented 12 cycles of filtration and regeneration, removing 96.3 % of RB5 dye and 90 % of total organic carbon. The regeneration of the membrane was performed via degradation of the contaminant using the photo-Fenton process and MIL88A as the photocatalyst. The membrane was able to separate emulsified contaminants in water such as diesel fuel. These results suggest that the proposed membrane is promising for water reuse from effluent treatment.

Photoelectrocatalysis devices play a key point in green power generation systems. At the nanoscale, the efficiency of the device is driven by the interface [1,2], which can be assessed by HRTEM images, in addition to EELS and EDS coupled to a scanning mode microscope (STEM) [3]. In this study, we investigated the interface of hematite with 3% Zr deposited on fluorine-doped tin oxide, and we added a NiFeOx solution to form a layer of co-catalytic material (Ni). Samples were prepared using a FIB. We obtained chemical and electronic state characterization at the interface via STEM-EELS-EDS maps. The results show a 2.5-nm thick interface containing a Fe-Sn-O mixture. Structural analysis of the interface by HRTEM imaging showed that the interface exhibited lattice distortions and high stress. The concentration map revealed that Zr segregated at the grain boundaries of the hematite and in the mixing region of the interface and that Ni is deposited on the free surface of the hematite. The energy maps show a shift towards Sn+4 to Sn+2 and Fe+3 to Fe+2 for both FTO and Hematite grain boundaries, caused by the loss of oxygen from the system.

Synthesis and characterization of iron (III) oxide/bismuth molybdate thin film heterostructure forthe photo electrocatalytic degradation of antibiotic oxytetracycline.

Elizabeth Carmen Pastrana Alta[1]

[1]UNIVERSIDAD NACIONAL DE INGENIERÍA (*Lima*)

e-mail: epastrana@uni.edu.pe

In this work, nano-heterostructures based on iron (III) oxide/bismuth molybdate (α-Fe2O3/Bi2MoO6) thin films were fabricated by a dip-coating technique using aqueous solutions. The heterostructures were deposited on fluorine-doped tin oxide glass substrates. From a detailed characterization using Fourier transform-infrared and X-ray diffraction, the formation of α-Fe2O3 (hematite) and bismuth molybdate was demonstrated.

The field emission scanning electron microscopy cross-section images confirm the formation of a well-defined α-Fe2O3 layer under the Bi2MoO6 layers. The optical band gap energies for the heterostructures obtained were estimated from the diffuse reflectance spectra and correspond to 1.6 eV.

The photoelectrochemical degradation of the antibiotic oxytetracycline (OTC) at different pH values was investigated in an aqueous solution under visible and solar light irradiation. Particular emphasis was given to the kinetics and mechanism during the photocatalytic degradation of OTC.

Moreover, the mechanism of photochemical degradation of OTC was investigated at different potential values under solar light.

Synthesis of MoS2/MoO3 composites for the removal of cationic dyes by adsorption process

Jéssica Cristina de Almeida[1], Thais Mota de Souza[1], Thaís Aparecida Rodrigues[1], Douglas M. S. Del Duque[2], Vagner Romito de Mendonça[2,1]

e-mail: j.cristinal@outlook.com

Dyes are used in a diversity of industries, such as plastic, textile, paper, and others. The annual production of synthetic dyes worldwide is about 7.107 tons and around 10,000 tons are being used by textile industries. Textile dyes are persistent pollutants that can bring several threats to human health and the environment.[1,2] In this context, the application of an adsorbent to remove dyes from contaminated wastewater is an interesting method that does not involve drastic changes in the usual water treatment plant. In the present work, we studied the synthesis and application of MoS2/MoO3 composite for the adsorption of the methyl blue(MB) organic dye. The synthesis of the samples was performed by the calcination of the MoS2 precursor under different temperatures and calcination times to evaluate their adsorption efficiency and find the best synthesis conditions. Samples were characterized via thermogravimetry (TG), X-ray Diffractometry (XRD), infrared spectroscopy (FTIR), and scanning electron microscopy (SEM). As result, it was possible to notice efficient adsorption properties in the materials calcinated under 300 ºC. XRD measurements confirmed the MoS2/MoO3 composite formation, while FTIR and TG analyses showed that it occurs only on the surface of the adsorbent particles. SEM images with EDS presented a uniform distribution of Mo, O, and S on the sample's surface. Finally, Isotherm adsorption measurements conducted with the main sample attained the maximum adsorption of 505.1 mg of MB adsorbed per g of adsorbent, which is a great value compared with the literature. In summary, the studied materials presented attractive adsorption properties under mild temperature and time synthesis conditions.

e-mail: larissa.silva@cetene.gov.br

Brazil has one of the cleanest energy matrices in the world. The solar irradiation predominant in the Brazilian Northeast makes the region one of the most promising in the exploitation of solar energy for conversion into electrical energy. Additionally, thanks to the intermittent character of the sun, it is necessary to store energy in the form of a vector, making it possible to use it in the absence of its main source.[1] Hydrogen, therefore, is one of the main fuels and enables carbon-free combustion, which benefits the environment. In this work, titanium dioxide (TiO2), a semiconductor with a band energy of 3.2 eV, is applied as a photocatalyst in the production of photoanodes using the spin-coating technique.[2] Films are produced over FTO in two steps. A TiO2 compact layer is deposited by adding titanium diisopropoxide and thermal treatment at 500°C for 60 min. The TiO2 mesoporous layer was optimized in terms of paste concentration and the number of deposited layers, and at the end of the process the photoanode was thermally treated at 450°C for 30 min. The photoelectrochemical performance of the photoanodes was linearly dependent on the layer thickness, with a maximum value of 0.34 mA.cm-2 with a thickness of 4.20 ± 0.17 μm afterthe deposition of 4 layers in a ratio of 1:4 (TiO2:EtOH). In order to broaden the spectrumregion, bismuth sulfide nanocrystals were applied as sensitizers, with a band energy of 1.9eV. After sensitization, performed through chemical adsorption for 24 h, the photoanodes showed 1.5 mA.cm-2, a value 4.4 times higher than pure TiO2. Thus, photoanodes have great potential for photoelectrochemical green hydrogen production, proving the concept of improving photoelectrochemical performance by sensitizing mesoporous TiO2 films with semiconductor nanocrystals.

Use of immobilized microalgae for effluent treatmentand concomitant biomass production

Paulo Alexandre Silveira da Silva[1], Beatriz Jacob Furlan[2], André Bellin Mariano[3], José Viriato Coelho Vargas[1]

[1]Universidade Federal do Paraná (*Engenharia Mecânica*) , [2]Universidade Federal do Paraná (*Engenharia e Ciência dos Materiais - PIPE*) , [3]Universidade Federal do Paraná (*Engenharia Elétrica*)

e-mail: paulo.alexandre@ufpr.br

The use of microalgae for effluent treatment has gained prominence in recent decades. Therefore, new technologies and processes have shown satisfactory results regarding the efficiency of bioremediation. One of the options used is based on the immobilization of microalgae in polymeric matrices, which aims to optimize the intrinsic characteristics of these microorganisms for the treatment of wastewater [1]. Thus, the objective of this work is the development and characterization of a polymeric matrix based on alginate and nano-chitosan for microalgae cultivation and effluent treatment, as well as evaluating its bioremediation potential. The methodology consists of trapping the cells inside a porous and semipermeable membrane in the form of a capsule, through physicochemical interactions. The cell immobilization system is an excellent alternative to traditional treatment methods, as it aims to increase efficiency and reduce costs in processes, decreasing energy consumption in unit operation, enabling cell reuse and significantly increasing the capacity for complexation and pollutant treatment [2]. Furthermore, it is possible to simultaneously treat wastewater and produce microalgae biomass, reducing the concentration of pollutants by approximately 80% and achieving yields of up to 1.6 g/L of biomass. From the biomass, various high-value-added bioproducts can be obtained, especially those related to biofuel production. This process is relatively new and still has fields to be explored and possibilities for technological implementations.

e-mail: LUIZH@UEL.BR

This study presents a simple, cost-effective method for producing iron vanadate semiconductor material with remarkable electroactivity.[1,2] This material was used as a photoelectrochemical sensor for detecting dopamine. The iron vanadate obtained using the Successive Ionic Adsorption and Reaction process was thoroughly characterized in terms of its structure and morphology. Photoelectrochemical characterization showed that the photoanode had high photoelectroactivity when irradiated with visible light. Under optimal conditions, dopamine was detected using chronoamperometry at +0.35 V (vs. Ag/AgCl), achieving two linear response ranges (1.2-30.3 and 30.3-72.8 μmol L^{-1}). The limits of detection and quantification were 0.34 and 1.12 μmol L^{-1}, respectively. The accuracy of the proposed electrode was evaluated by measuring dopamine in artificial cerebrospinal fluid, resulting in recovery values ranging from 98.7 to 102.4%. The selectivity of the sensor was also tested by detecting dopamine against several interferent species, and the results demonstrated good precision and promising potential for the proposed method. Additionally, electronic structure calculations based on DFT were performed to aid in interpreting the results. The dominant dopamine species were identified under the experimental conditions, and their interaction with the iron vanadate photoanode was proposed. The improved light-induced dopamine detection was also evaluated regarding the charge transfer process.

e-mail: franciscoedu490@ufpi.edu.br

Tungstates have aroused great interest in recent decades, as they play a key role in emerging technologies for applications in sectors ranging from the environmental area through the development of new catalysts, to the energy area with the development of materials with optical properties for application in lighting devices in the solid state. Recently, the increase in the level of pollution around the world has not only contributed to environmental issues, but also aroused considerable interest in photocatalysis that act as promising treatments, based on studies concerning tungstate. The objective of the study in question refers to the applicability of tungstate of various types with the property of environmental treatment by means of pollutant controls, demonstrating its efficiency with respect to the improvement of the environment. The information obtained was based on searches made through databases with the use of specific keywords in order to filter as much as possible the possible results directing them to the theme, observing the data, it is noted the increasing use of tungstate for various applications through time. It is concluded then that a study regarding the application of tungstate in photocatalysis of pollutants becomes very promising and innovative due to its vast area of applications with respect to the health of the planet as a whole.

Application of ZnO-SiO2 oxides in the degradation of Aldrin pesticide by heterogeneous photocatalysis

Felipe Breno Campos Marinho[1], Marcilane Faustino da Silva[2], Jéssica Luisa Alves do Nascimento[3], Ana Cristina Figueiredo de Melo Costa[4], Iêda Maria Garcia dos Santos[5], Sayonara Andrade Eliziário[6], Mary Cristina Ferreira Alves[2]

e-mail: felipebrenocm@gmail.com

The environment is continually impacted by water sources, and one of the main pollutants is agricultural and industrial waste. In this context, pesticides are widely used in the agricultural sector and due to their toxic nature, chemical characteristics and because they are biologically stable, their degradation has been one of the great challenges for the scientific community [1]. Thus, the present work aims to investigate the catalytic activity of the binary oxides of ZnO-SiO2 obtained by the Pechini method, aiming at application in the photocatalysis process for the degradation of the Aldrin pesticide. The materials obtained were characterized by X-Ray Diffraction (XRD), Infrared (IR), UV-Visible and Raman Spectroscopy, BET and Scanning Electron Microscopy (SEM). The photocatalytic tests were carried out in a photocatalytic reactor with UVC lamps with a reaction time of 1 to 4 h. The oxides were successfully obtained, according to the DRX standards and the ICDD charts of ZnO and SiO2. In relation to the IR analysis, it was possible to observe characteristic molecular vibrations of SiO2(490 cm-1) and ZnO(430 cm-1), and from the absorption spectra in the UV-visible region it was possible to calculate the band gap of the catalysts the values obtained varied between 2.88-2.92 eV. In the Raman spectra, we observed a greater degree of symmetry for samples containing a greater amount of Si4+, however, the FWHM values calculated from XRD revealed a lower degree of long-range symmetry for samples with a smaller amount of Si4+. As for the photocatalytic tests with the pesticide Aldrin, the samples Zn0.90Si0.100, Zn0.80Si0.200 and Zn0.70Si0.300, presented 31.6; 42.3 and 56.4% degradation, respectively.

e-mail: jozielmateriais@gmail.com

A composite based on the green polysaccharide mesocarp of babassu and $TiO_2$was synthesized through the sol-gel technique [1,2]. XRD, UV-Vis Diffuse Reflectance Spectroscopy-DRS-Uv-Vis, and N_2adsorption-desorption characterized the synthesized material. Photocatalytic tests were carried out with the dye methylene blue (MB) (concentration 12.0×10^{-6}mol L^{-1}) under UV-Vis light, the samples were removed in time determinate and were centrifuged at a rotation of 5000 rpm. Subsequently, they were analyzed by a spectrophotometer UV-Vis in a 200 to 800 nm. The dye concentration was determined using the absorption band at 664 nm. XRD showed that the material presented the anatase crystallographic phase of TiO_2. The material presented a crystallite size of 8.01 nm, calculated by the Scherrer equation. From DRS-Uv-Vis, it was possible to calculate the band gap energy value of the material by the Kubelka-Munk method, obtaining the value of E_g= 3.19 eV. From the N_2adsorption-desorption technique, the BET method calculated the specific surface area, obtaining a value of 95.41 m2 g−1. The pore volume and average pore diameter were calculated by the BJH method, obtaining values of 0.11 $cm^3g^{-1}$and 4.6 nm, respectively. The photocatalytic test showed that the composite promoted an MB discoloration of 69.34%. It was concluded that the material synthesized from the green polysaccharide and $TiO_2$is promising in the proposed application.

$BiVO_4$ and V_2O_5 synthed by microwave-assisted hydrothermal method for selective adsorption towards methylene blue

Leonardo Jesus de Campos[1], Ana Paula Andrade Barbosa[1], Beatriz Caetano Benuto[1], Roberto de Matos[2]

[1]Universidade Estadual de Londrina (*Química*) , [2]Universidade Estadual de Londrina (*QUIMICA*)

e-mail: leonardo.jesus@uel.br

Dyes from industrial processes are potential sources of water pollution due to their aromatic structures and species loads, which can make their removal difficult. For this, adsorption processes with a solid material stand out, and the adsorptive efficiency will depend on the chemical nature, stability, charge, and surface of the material [1]. Thus, this work aims to synthe oxides in different proportions of bismuth and vanadate to apply them for the adsorption of methylene blue cationic dye (MB), in addition to testing the selectivity of oxides with methyl orange anionic dye (MO) and monitoring by UV/VIS spectrophotometry. For the synthesis of $BiVO_4$, two solutions were prepared, one with 8 mmol of NH_4VO_3in NaOH and the other with 8 mmol of $Bi(NO_3)_3.5H_2O$ in HNO_3. $V_2O_5$was synthed using 8 mmol of NH_4VO_3in NaOH and HNO_3[2]. The synthesis of the $BiVO_4/V_2O_5$composites occurred with a mol excess (1 and 5%) of NH_4VO_3. The mixtures were submitted to a hydrothermal reactor under microwave at 160°C/15 min. For the adsorption, AM 4 $\mu molL^{-1}$(pH 8) and 0.2 g $L^{-1}$of oxide synthed in the solution were used. The results showed that a higher proportion of bismuth in the Bi/V molar ratio did not significantly alter the adsorptive capacity of these materials. On the other hand, a higher proportion of vanadium in the Bi/V ratio and even the absence of bismuth (V_2O_5) significantly increased the adsorptive capacity. For the selectivity test, a solution with MO and MB was used. We conclude that the synthed $V_2O_5$was more efficient in the adsorption and desorption of the methylene blue dye and was selective when applied with MO, properties that were not observed for the samples rich in bismuth and commercial activated carbon.

e-mail: joordanmeireles@gmail.com

The use of semiconductor materials and strategies to improve their photocatalytic properties have been widely explored. And, because of its chemical stability, optical, electronic properties, zinc tungstate (ZnWO4) has emerged as a promising photocatalytic material. Despite being a good semiconductor, with Eg = 3.8 eV, the electronic characteristics of ZnWO4 limit to the light absorption in the UV region, making it a restricted photocatalyst [1]. To improve the photocatalytic activity of ZnWO4, we aimed to decorate the ZnWO4 with different ZnO nanostructures. It has been reported that the particles morphology has an important role in photocatalysis [2]. The synthesis of these materials was done, for the first time, by a combination of methods that are: the Pechini-modified method and solvothermal synthesis. A proportion of 10 %wt of ZnO was fixed to be incorporated on ZnWO4. According to X-ray diffraction (XRD), infrared (IR) and ultraviolet-visible (UV-vis) spectroscopy and zero charge point analysis (PCZ), the target ZnWO4@ZnO materials were successfully obtained with different surface charge characteristics. The samples were then applied in the photodegradation methylene blue (MB) dye under irradiation. It was possible to note that by adding 10 %wt of ZnO boosted photocatalytic degradation of MB dye when compared to pristine ZnWO4. The morphology of ZnO nanoparticles observed on the ZnWO4 had a strong influence on the photocatalytic efficiency of the final ZnWO4@ZnO material, also indicating a synergistic effect between both ZnWO4 and ZnO.

Catalytic reduction of 2,4-dinitrophenol with gold nanoparticles

Raphaella Rodrigues Lourenço[1], Rodolfo Debone Piazza[2], Eder Luiz Menezes da Silva Junior[1], Rodrigo Fernando Costa Marques[3]

[1]Universidade Estadual Paulista / Instituto de Química (*Química Analítica, Físico-Química e Inorgânica*) , [2]Universidade Estadual Paulista (*Instituto de Química*) , [3]Universidade Estadual Paulista / Instituto de Química (*Química Analítica, Físic0-Química e Inorgânica*)

e-mail: raphaella.rodrigues@unesp.br

2,4-dinitrophenol is among the most harmful phenolic derivatives for humans and the environment. It is a toxic organic substance common in industrial effluents and can also be found in aquatic environments near urban and agricultural areas1. The objective of this work was to carry out the degradation through a catalytic reduction using sodium borohydride as reducing agent and gold nanoparticles as catalysts to reduction of 2,4-dinitrophenol to 2,4-diaminophenol, which is less harmful and has important industrial applications such as in the manufacture of dyes and color accelerator in photographic developers2. The colloidal solution of gold nanoparticles synthesized from 2.5×10^{-4} mol L^{-1} citrate was more uniform and homogeneous morphology, with a greater number of particles and better distribution. Regarding to size distribution, this sample showed lower standard deviation in relation to the sample with a higher concentration of citrate, so it was chosen for the reduction of the nitrophenolic compound, showing good degradation efficiency, especially when using a more concentrated solution of nanoparticles.

TiO_2nanotubes (TNTs) are oxide films grown on Ti alloys substrates through electrochemical anodization and have found important practical applications such as pollutants photodegradation. This derives from their properties as semiconductor with narrow band gap and high surface area, promoting chemical reactions between the TNTs and organic molecules when it is exposed to light. Commercially pure Ti has been the most studied substrate for TNTs formation, with varying electrochemical parameters resulting in different properties and characteristics of the nanotubes [1]. This study aims to investigate the growth, mechanical, and compositional properties of TNTs grown on Ti-29Nb-13Ta-4.6Zr alloy (TNTZ), with a focus on their potential applications in pollutants degradation. After synthesis by anodization, well-ordered and homogeneous nanotube formation was observed by SEM, without residual ribs, which is beneficial for photocatalysis applications, reducing the electron-hole contact. Deconvolution of XPS spectra showed high variability in oxide compositions increasing with film depth, possibly attributed to defects in the crystal lattice due to oxide formation, which in turn lead to different properties of the nanotubes. Moreover, XPS depth profiling showed dominance of high oxidation states on the tube surface, indicating that the nucleation process leads to formation of different morphologies, likely associated with induction of defects in the oxide lattice, forming metastable oxides [2]. After annealing, anatase crystal structure was obtained, which is known to exhibit improved properties for photocatalytic applications. Regarding photodegradation, the use of nanotubes grown on TNTZ increased its efficiency by up to 82% in dye degradation compared to TNTs grown over CP2.

High levels of nitrate ions (NO3-) mainly due to the increasing global fertilizers use, and chromate ions (CrO42-) coming from different industries, such as leather tanning and textile industries, in the surface and groundwater, are increasingly becoming a widespread global problem. Thus, the development of effective materials for removal of nitrate and chromate ions from aqueous media is essential. This work aims to prepare ordered mesoporous silica, type SBA-15, and natural clay minerals (kaolinite and vermiculite) functionalized with 3-aminoprylltriethoxysilane (APTES) for adsorption of nitrate and chromate ions from contaminated aqueous solutions. SBA-15 has been widely studied due to its unique properties, such as non-toxicity, chemical stability, structural and textural properties, such as high specific surface area and pore volume, that are interesting for the adsorption of pollutants. Clay minerals also have good adsorption characteristics such as cation exchange capacity, in addition to high surface area, and low cost, which is economically advantageous. Functionalization of SBA-15 and clay minerals materials with amino groups (APTES) was carried out in toluene by grafting method. All prepared materials were characterized by several physicochemical techniques. Small angle X-ray scattering curves showed that the typical mesoporous structure of SBA-15 was preserved after the grafting procedure. Fourier transform infrared spectroscopy and thermogravimetry data of all materials show the presence of APTES, evidencing the functionalization of the materials. Scanning electron microscopy images showed that the particles morphology remains intact after the functionalization and adsorption process. Adsorption experiments were performed to investigate the adsorption of the anions onto SBA-15 and the functionalized clay minerals. The results were promising for the adsorption of anions, with the amino-functionalized SBA-15 showing a higher adsorption performance.

Co and Fe-doped $MoSe_2$ for photocatalytic removingwater pollutants under UV–Light

Jaine Aparecida da Silva Pereira[1], Rafael Aparecido Ciola Amoresi[1], Marcia Tsuyama Escote[2]

e-mail: jaine.pereira@ufabc.edu.br

Two-dimensional materials have been extensively studied and considered for various applications, such as energy conversion and storage, electronic devices, photocatalytic, and optoelectronic systems. Among them, dichalcogenides compounds (MoS_2, $MoSe_2$, $MoTe_2$) are a particular class of 2D systems that have been studied and applied in several areas of knowledge. Molybdenum diselenide has great potential for the degradation of water pollutants, but its performance is limited by active sites and recombination of photogenerated electron-hole pairs. Also, the catalyst doped with magnetic nanoparticles enables its easy separation from the reaction mixture, thus making its recycling and reusability simple and efficient. In this study, $Mo_{(1-x)}M_xSe_2$ (M=Fe, Co) compounds were synthed by a microwave-assisted solvothermal method. Their structural, microstructural properties are investigated using X-Ray Diffraction, Raman Spectroscopy, UV-vis Spectroscopy, and Field Emission Scanning Electron Microscopy. Photocatalytic dye degradation was analyzed using these samples on rhodamine B (RhB) and methylene blue (MB). Photocatalytic experimental results revealed a better adsorption and photodegradation of rhodamine B (RhB) and methylene blue (MB) were achieved with doped-$MoSe_2$than with pure $MoSe_2$under dark conditions and UV-light irradiation.

e-mail: Jailtonalvesjr@outlook.com

Photocatalysis has been widely studied in water treatment through the degradation of organic pollutants, such as dyes. Several metallic oxides have been studied for this purpose, such as zirconium and barium oxides [1], but these oxides have a low surface area, so silica has been used to assign a greater area for these materials [3]. In this work, the mixed oxides SiO_2-ZrO_2(SZ) and SiO_2-ZrO_2-BaO (SZB) were synthed by Pechini's methods (MPE) and metal-chitosan complexation (CMQ). To elucidate the characteristic and textural properties of these materials they were then characterized by different techniques. In the physisorption analyses, using the BET method, a greater surface area was observed for the SZB oxide synthed by the CMQ method (203 m^2/g), while the SZ oxide presented a greater area when synthed by the MPE method (335 m^2/g). By XRD it was observed that the materials were amorphous. In the diffuse reflectance spectroscopy it was observed that only the oxides synthed by CMQ presented band gap energy characteristic of semiconductors, being 2.93 eV for the SZ-CMQ oxide and 3.45 eV for the SZB-CMQ. After the characterizations, the materials were applied in the photodegradation of methylene blue, being irradiated at 273 nm and 365 nm. The reactions were carried out with a total time of 70 min. The SZ-CMQ material showed greater dye photobleaching when irradiated at 365 nm (32% photobleaching), while the SZB-CMQ material had greater photobleaching when irradiated at 273 nm (35.5% photobleaching). For both materials, an equilibrium pattern was not observed in the photocatalytic efficiency curve, so it was necessary to increase the reaction time.

e-mail: junior.ferreira@ufpi.edu.br

The present study reports the development of a composite composed of sodium titanate nanotubes modified by points of carbon (C-dots / NaTNTs), from a source based on titanium oxide and babassu coconut mesocarp, respectively. The composite was successfully synthesized through a hydrothermal procedure. Their structural, microstructural, morphological and optical properties were analyzed by X-ray diffraction (XRD), Scanning Electron Microscopy (SEM), Ultraviolet and Visible Spectroscopy (UV-Vis), Raman and Fourier Transform Infrared (FTIR).The characterization results indicated the formation of sodium titanate nanotubes, carbon dots and the successful deposition of C-dots on NaTNTs. As intended, the hybrid nanomaterials showed an increase in the energy absorption range compared to pure NaTNTs. In this sense, this study presents an available method to modify titanate nanomaterials, and the new C-dots/NaTNTs hybrid material developed may be promising for photocatalytic applications aimed at removing organic pollutants that cause environmental impacts.

Pollution caused by improper disposal of different pollutants, such as organic dyes and pharmaceutical drugs, brings the search for new technologies for the decontamination of water bodies. Several methodologies, especially heterogeneous photocatalysis have proven to be used to degrade these pollutants in water [1,2]. Among different photocatalytic oxides,ZnO needs to be highlighted for presenting intrinsic carrier concentration depeding on the particle morphology that can strongly influence the photocatalytic properties [3]. Thus, the present work aims to investigate the photocatalytic efficiency of different ZnO nanostructures obtained by the microwave-assisted solvothermal method in different synthesis media at 100°C for 1h. The samples were characterized by X-ray diffraction (XRD), infrared spectroscopy (IR), UV-Vis spectroscopy, scanning electron microscopy (FE-SEM) with energy dispersive X-ray spectroscopy (EDS), electron paramagnetic resonance (EPR)and transmission electron microscopy (TEM). Our results demonstrated that all samples presented well-crystallized particles with different and shape as well as distinct growth orientation and charge carrier concentration. From the photocatalysis data, it was possible to observe that the flower-like ZnO nanostructures presented a photodegradation efficiencyof 70% of methylene blue dye for 4 h, while the star-like and sphere-like ZnO nanostructures showed an efficiency of 45% and 15%, respectively.

Water is an extremely necessary asset for the maintenance of human life in different spheres, however, access to drinking water is still a rare item for millions of people. With globalization and industrial expansion, environmental pollution become more evident, as can be seen in the aquatic environment, for example[1]. One of the most common forms of effluent contamination is through improper disposal of dyes from cosmetic, pharmaceutical, and textile industries, the latter being one of the biggest contributors to this problem. These dyes are organic substances that mostly have the azo group in their structure (-N=N-), which are capable of giving color to a substrate through chemical affinity. These substanceshave carcinogenic, mutagenic, and genotoxic potential, and methods that contribute to thecomplete degradation of these species are still needed. Catalytic methodologies for this degradation process are viewed positively. The literature describes some methods for thispurpose, such as nanocatalysis, in which the use of nanoparticles, specifically silver nanoparticles (AgNPs) have been highlighted [2]. In this work, AgNPs were synthesized with3 stabilizers, ascorbic acid (AA), polyvinyl alcohol (PVA), and sodium citrate, and were applied in the degradation of the azo dye, remazol red RB. The optical and structuralcharacterizations confirmed the formation of stable nanospheres. The degradation of the azo dye with the catalysis was evaluated via UV-Vis in a maximum time of 30 minutes. Ourresults showed that these AgNPs were efficient catalysts for the degradation of the organicdye in an aqueous medium, with a faster, cheaper, and simpler method than those alreadydescribed in the literature.

In view of the scenario of environmental pollution, the use of the Adsorption-Process, as a technology for removing contaminants, stands out especially because it is low cost, it allows the recovery of the adsorbent and also due to the high variety of adsorbent materials [1], among them we highlight the porous materials, giving emphasis to the mesoporous silica MCM-41 (Mobil Crystalline Materials) and the Zeolitic Imidazolate Framework-8 (ZIF-8). Both materials have a surface area with specific adsorption sites, selectivity, porosity, favorable adsorption kinetics, and renewability [2,3]. The present work aims to obtain a heterostructure from the synthesis by in situ coprecipitation of ZIF-8 on the surface of MCM-41, improving its individual characteristics, and thus, developing a promising functional material to be used in adsorption. This material was characterized by several physical-chemical techniques, such as XRD, FTIR, N2 adsorption (BET analysis), showing an interaction between the pristine materials while maintaining their structures and textural properties.

Abstract

The accentuated population growth in the 20th century enabled large-scale industrial production characterized by the intense use of synthetic chemical compounds such as insecticides, organic dyes, drugs, among others. The waste generated by these activities is usually discarded in the ecosystem, leading to the accumulation of a large number of pollutants in natural water bodies and, in turn, causing significant damage to the environment and human life. Therefore, in order to contain the deleterious effects of organic pollutants on water bodies, it is essential to develop materials with good photocatalytic activity, such as tungstates [1]. In this context, the present study aims to obtain pure Bi_2WO_6 nanoparticles and Bi_2WO_6 nanoparticles doped with 4% Zn^{2+} through the sonochemical method. The photocatalytic activity of the pure and doped samples was verified from the degradation of methylene blue dye (MB). The XRD results showed the presence of a single orthorhombic phase and it was verified that the doping was effective, since there was no formation of a deleterious phase. The micrographs performed by FEG-SEM of pure and doped samples showed rod-shaped and spheroidal structures. According to the UV-vis analysis, the doped sample showed the highest redshift at the absorption edge compared to the pure sample. The pure sample had the best performance in the degradation of the methylene blue dye compared to the doped sample, when subjected to UV irradiation, with a percentage of dye degradation in the presence of Bi_2WO_4-pure exceeding 80%.

Solid Oxide Fuel Cells (SOFCs) with an oxide-ion-conducing electrolyte are efficient, clean, and sustainable energy-conversion devices. However, the high performance of SOFCs occurs at a high temperature (≥ 800 °C), which can cause material degradation and increase balance-of-plant costs. Proton-conducting SOFCs (Protonic Ceramic Fuel Cells, PCFCs) alleviate this problem on operating at lower temperature (600-800 °C) since the activation energy for conduction of protons is lower than that of oxide ions. Perovskite proton conductors $BaCe_xZr_{1-x}O_{3-\delta}$are very promising but their refractory nature means that densifiying electrolytes requires high temperatures and long sintering times. To reduce the temperature and time of conventional sintering, alternatives have been explored, such as solid-state reactive sintering using sintering aids [1]. In this work, we investigated the effect of the dopant and ZnO sintering aid in the system $BaCe_{0.2}Zr_{0.7}M_{0.1}O_{3-\delta}$(M=Y, Gd, Sm, Yb) on solid-state reactive sintering and densification. Stoichiometric powder mixtures were prepared with and without the addition of 2 mol% ZnO as sintering aid. Sm- and Gd-doped samples with the addition of ZnO sintered to >90% relative density with one heat treatment at 1650 °C for 4 hours from the compacted starting powders. Whereas other dopants and samples without ZnO did not densify. The total conductivity determined by impedance spectroscopy for the sample $BaCe_{0.2}Zr_{0.7}Sm_{0.1}O_{3-\delta}$with 2 mol% ZnO was 2.60 mS. cm^{-1}at 600 °C in air, a value higher than that of the analogue obtained via the conventional ceramic routewith multiple calcination and milling steps.

Solar water splitting is an alternative method to produce H2 using sunlight and specialized semiconductors [1]. Ionic doping in semiconductors is considered efficient strategy to enhance the charge transport and avoiding its rapid recombination. This study, a simple polymeric precursor method was employed for the fabrication of pristine copper tungstate (CuWO4) film and that of varying doping concentration (1;3;5%) of lithium (Li:CuWO4) and magnesium (Mg:CuWO4). Optical, morphological, and structural properties of the synthed materials were characterized using diffuse reflectance spectroscopy (DRS), emission-scanning electron microscopy (FE-SEM), X-ray diffraction (XRD), respectively. Spherical shaped nanostructures were observed, just like confirmed triclinic structure and the presence of dopants with elongation of crystalline lattice [2]. The impurities occupied interstitial sites in the host CuWO4 lattice and induced shift for lower optical band gap energy [3]. The presence of dopants was clearly observed with photoelectrochemical response, modifying n-type behavior of host film for p-type in the doped CuWO4 films. Doping with Li or Mg in host CuWO4 electrodes favored the inhibition of the charge recombination. Moreover, an excellent material for photoelectrochemical application.

In recent years there has been an increase in the development of electrospinning materials due to the functional characteristics obtained through a quickly and simply way [1]. This work successfully prepared electrospinning particles of polyvinylpyrrolidone containing TiO2 synthesized by the Pechini method. Different types of TiO2 annealed at 400 and 500 °C were incorporated into a polyvinylpyrrolidone polymer resin and the photocatalytic activity of membranes functionalized with TiO2 was demonstrated with the degradation of venlafaxine. The membranes were extensively characterized using techniques such as attenuated total reflectance, Fourier transforms infrared spectroscopy, scanning electron microscopy and oxide particles by X-ray diffraction, UV-visible absorption and the Brunauer-Emmett-Teller adsorption method to correlate the characteristics of oxide particles with their performance. The results of photodegradation with venlafaxine in sodium phosphate buffer monitored by voltammetry showed excellent photocatalytic activity of TiO2 particles immobilized on the membrane structure. After 90 min of UV irradiation, a degradation of up to 85% of the drug was observed. The lowest annealing temperature (400 °C) produced a TiO2 phase mixture rich in anatase on the PT 400 C membrane with increased surface area, generating the adsorption sites of the venlafaxine molecule. A reuse test of the functional materials confirmed that the TiO2 particles were successfully incorporated into the electro-spun membrane and revealed that organic matter photodegradation is possible. Persistent pollutants such as dye residues from the textile industry, drugs and even microplastics cannot be retained or eliminated with conventional methods of effluent treatment, requiring the use of more specific and advanced techniques for these treatments. Heterogeneous photocatalysis has shown efficiency for this purpose. It consists of the use ofa semiconductor material that, when irradiated with light at specific energy, initiates a series of electronic reactions, generating highly oxidative species in solution, such as hydroxyl radicals. The present work investigated the photocatalytic efficiency of titanium dioxide nanotubular structures in its anatase phase and in proportions with 27% of the rutile phase, for the photodegradation and minieralization of methylene blue dye. Nanotubular titanium dioxide plates measuring approximately 1.3 cm2 were kept in contact with the dye solution at 15 mg/L, in a quartz reactor, at 25ºC, with different irradiation times using a solar simulator. The reaction product was analyzed by UV-Vis and TOC, relating the decrease in the intensity of the bands with the reduction in the dye concentration in solution and, consequently, its photodegradation. The reduction in TOC concentration was attributed to dye mineralization. In 6 h of irradiation, 87% of discoloration of the solution was reached, and 37% of removal of OC, using the material with 27% of rutile in mixture of phases. Which represents an increase in efficiency by approximately 40% compared to the material with the pure anatase phase. Thus, better results are expected with optimizations related to the of the anodized area, light energy used in photocatalytic tests or even increased exposure time.

Emergent contaminants adsorption from aqueousmedia by biochar/bentonite composite

The lack of using wastewater treatment processes in Peru let some drugs, such as oxytetracycline (OTC), increasing its concentration in water bodies year by year; for this reason, they are considered a risk associated with wastewater discharges into the aquatic environment. (Nieto-Juárez et al., 2021). Therefore, some advanced treatments are necessary to remove that contaminant. Among the removal methods, adsorption is an efficient method due to the feasible preparation of biochars from inexpensive materials, giving a large surface area material. The aim of this work is to adsorp OTC from water samples by a composite comprising 2 active materials: natural bentonite and biochars obtained from reed wood (Phragmites Australis). The preparation process was as follows: pretreated reed wood (cut up, blended and rinsed) and bentonite (rinsed and activated with 2.0 M HCl solution) in a1:1 ratio was mixed with ZnCl2 solution and stirred for 10h. After dried, a pyrolytic process was carried out at 400 °C in N2 atmosphere for 4 h at 10 °C min-1. Diffraction patterns revealed the presence of quartz, montmorillonite, and feldspar structures, being the crystalline face (001) of montmorillonite the main peak. FTIR spectra showed the stretching of de C=C bond in the aromatic ring at 1587 cm-1 and 2 bands at 1022 cm-1 and 794 cm-1 corresponding to bentonite. BET isotherm gave a surface area of 515 m2.g-1. Kinetic studies showed that the composite was able to adsorb upon 87.4 % of OTC from 20 ppm solutions in 90 min with a dosage of 50 mg/100 mL. The Temkin isotherm best fit the results in equilibrium state. Results suggested that the material could be used to effectively remove OTC from aqueous solutions.

e-mail: LUIZH@UEL.BR

This study describes a straightforward and affordable approach to constructing a photoelectrochemical (PEC) platform to detect SARS-CoV-2 glycoprotein using an iron vanadate semiconductor. The semiconductor was obtained via the Successive Ionic Adsorption and Reaction process on indium-doped tin oxide substrate (ITO). Its structure and morphology were thoroughly characterized.[1,2] To assess the interaction between SARS-CoV-2 and anti-SARS-CoV-2, the immunosensor surface was incubated with a SARS-CoV-2 solution. Amperograms were recorded by applying different potentials (+0.4 and +0.5 V vs. Ag/AgCl) in the absence and presence of visible light in phosphate-buffered saline (0.1 mol L^{-1}, pH 7.01). Formic acid (1 mmol L^{-1}) was also evaluated as a suitable sacrificial agent able to scavenge photo holes. The optimized anti-SARS-CoV-2-FeVO/ITO PEC platform was modified with 5 μg mL^{-1}antibody to detect SARS-CoV-2 glycoprotein. A decrease in photocurrent was observed as the concentration of SARS-CoV-2 increased from 1 fg $mL^{-1}$to 460 pg mL^{-1}. After ten successive essays, the RSD was calculated and found to be 3.2 and 3.4% for 60 and 260 pg mL^{-1}SARS-CoV-2 solutions, respectively. Furthermore, the biosensor could differentiate serum obtained from COVID-19 positive versus negative clinical samples, indicating that this platform holds promise as a rapid, efficient, and reliable method for detecting SARS-CoV-2 protein.

Zinc Tungstate ($ZnWO_4$) was synthed by the Pechini method. To optimize the synthesis of ZnWO4, precursors such as Zinc Acetate dihydrate $Zn(NO_3)2.6H_2O$ and Zinc Nitrate hexahydrate ($C_4H_6O_4Zn.2H_2O$) were tested, in addition to calcination levels of 400°C/2h followed by 700°C/4h and direct plateau of 700°C/4h. This second conditions and the use of $Zn(NO_3)2.6H_2O$ as precursor resulted in the synthesis of singe phase $ZnWO_4$, which was confirmed by characterizations by X-Ray Diffraction, Infrared (IR) Spectroscopy and Raman Spectroscopy in order to confirm the formation of $ZnWO_4$by the Pechini method. From the Absorption Spectroscopy in the UV-vis region, the band gap of $ZnWO_4$was calculated by the Wood and Tauc method and a value of 3.20 eV was obtained. Morphological analysis by scanning electron microscopy showed the formation of agglomerated particles. The zero charge point (ZCP) for ZnWO4 was at pH = 2.19. As pH values increase, the semiconductor has a negative surface. The evaluation of photocatalytic activities of zinc tungstate was carried out under UVC irradiation (λ= 254 nm) for terephthalic acid (AT) hydroxilation for evaluation of hydroxyl radicals ($^{\cdot}OH$) by fluorescence spectroscopy. The photodegradation of methylene blue dye (MB), using concentrations of 0.5, 0.8 and 0.85 mg mL-1 was also evaluated and the effect of pH on the photocatalytic activity was verified, considering pH = 5, 7 and 11. $ZnWO_4$had an efficiency of 99.3% in MB discoloration after 2h of irradiation. The meaningful formation of OH radicals and the MB adsorption, which depends of the material's surface charge, were determining factors for $ZnWO_4$to achieve a better photocatalytic performance in the degradation of the MB cationic dye.

The search for sustainable and economically feasible materials for wastewater treatment has been an important line of research in materials engineering. In this context, the use of recycled materials as adsorbents has been a promising alternative, since these materials have adsorbent properties and can be obtained from solid waste, thus reducing the environmental impacts. In this work, we evaluated the potential use of different recycled materials, such as plastics and ceramic materials, for the adsorption of contaminants in effluents. Characterization studies of the materials, adsorption isotherm analyses, and pilot scale tests were performed. The results indicated that the recycled materials present adsorption capacity comparable to conventional materials used in wastewater treatment.The results obtained indicate that the use of recycled materials as adsorbents can be a promising alternative for effluent treatment, contributing to the reduction of environmental impacts and the development of sustainable materials.

Fast synthesis of NaNbO3 nanoparticles with high photocatalytic activity

Research using semiconductors as photocatalysts has been carried out since the 70s. In this photocatalytic process, photons with energy equal to or greater than the band gap energy absorbed by the semiconductor, generate electron/hole pairs, thus creating oxidizing and reducing sites in its surface. These sites can degrade various pollutants into effluents, generate H2 and also reduce harmful gases. Many factors affect the activity of photocatalysts such as particle size, due to the surface/volume ratio, making nanoparticles very promising. Sodium niobate (NaNbO3) is a promising photocatalyst however, the natural shape of particles are large cubes, but research has already reported nanoparticles with high photo-catalytic activity [1]. Therefore, the objective of this work was to obtain NaNbO3 nanoparticles in a shorter time and apply different heat treatment temperatures in order to analyze the influence on the photocatalytic activity. The samples ob-tained had their photocatalytic activity measured through the photodegradation of Rhodamine B (RhB),a dye widely used in industries and known for its high tox-icity, good stability, and nonbiodegradability. In this study, we obtained NaNbO3 nanoparticles in the shortest time ever reported in the literature and demonstrated that with a simple thermal treatment it is possible to change the shape of the par-ticles, from nanowires to nanograins. All samples showed high photocatalytic ac-tivity, especially the nanograins, due to their smaller particle size and higher crys-tallinity. Reuse tests demonstrated the stability of the photocatalysts. Therefore, this study contributes with information for obtaining highly favorable NaNbO3 na-noparticles for photocatalytic applications.Acknowledgements: CAPES, CNPq, FAPERGS, UFPEL, UNESP Campus Bauru, UNIFESP Campus São José dos Campos, UNIPAMPA Campus Bagé and Thissiana Fernandes.References:[1] D. Recovery of mining waste could be a significant alternative to solve the issue of tailings in the Brazilian Amazon rainforest. In this study, manganese (Mn) oxide tailings were collected from the Azul manganese mine in Pará state, located in the northern region of the Carajás Mineral Province. The material underwent thermal treatment, resulting in the production of sodium-layered octahedral manganese oxide (Na-OL-1), which was then subjected to an ion exchange process using an iron precursor (FeCl) to obtain Fe-birnessite (Fe-OL-1). DRX, EDS, and Raman analyses confirmed the successful substitution of iron in the lamellar structure. Fe-OL-1 was used as a catalyst in the treatment of 50 mg/L of p-nitrophenol (PNP) in batch mode using heterogeneous dark-Fenton and photo-Fenton processes with hydrogen peroxide as an oxidant. Both processes achieved a PNP removal efficiency above 90% after 60 minutes of treatment, but the use of simulated sunlight (photo-Fenton) led to a mineralisation rate of 62%, compared to ~40% without light. At the end of both treatments, the sample was determined to be non-toxic based on an artemia salina toxicity assay. **Acknowledgements**: This work was supported by FNDCT through Finep [process 0122056900]. VNL, CEML, CISF and TSA are grateful to CNPq for their PCI fellowship. Cetene is a member of Sistema Nacional de Laboratórios em Nanotecnologias (SisNANO) of MCTI.

Fe-TiO_2/vermiculite for photocatalytic application

The immobilization of TiO_2on vermiculite clay mineral (Verm) is a strategy to improve the efficiency of the photocatalyst [1]. Doping the semiconductor with metallic ions, such as Fe^{3+}, is an alternative to modify the optical properties of the material and enable its excitation in regions of lower energies [2]. The present work aimed to evaluate the photocatalytic properties of TiO_2/Verm. The material was synthed via sol-gel and then calcined at 400°. XRD, diffuse reflectance, and SEM characterized the composite. The photocatalytic tests were carried out against methylene blue (30 ppm) using a 160w mercury vapor lamp as a source of Vis radiation. Dye discoloration was evaluated from the dye absorption band at 663nm. From the diffractograms, vermiculite, and TiO_2in anatase are identified form. From the reflectance data, the presence of Fe^{3+}caused a decrease in the material''s band gap (From 3.2 to 2.95 eV). There is no significant change in material morphology compared to Verm. The results of the photocatalytic testicles appreciated that TiO2 promoted 6% discoloration of the MB (1.8 ppm). While Fe2.5-TiO_2/Verm promoted 49.9% of discoloration after 120 min, being 3.31 ppm from photobleaching and 11.66 ppm by adsorption (in the dark). The results demonstrate significant advances in developing photocatalysts for environmental remediation applications.

Functional carbon-based catalyst derived from coffee grounds for efficient degradation of organic dyes via sono-fenton process

The contamination of water bodies by effluents and its subsequent environmental impacts have led to a growing need to develop effective water treatment strategies. Advanced oxidative processes (AOPs) have gained widespread recognition for their ability to mineralize non-biodegradable molecules. Among the AOPs, Fenton processes have been extensively studied for their in-situ formation of reactive oxygen species (ROS) in the presence of Fe2+ ions. However, the classic Fenton process has several limitations, including a restricted pH range, catalyst recovery, and reagent volume. In this context, the ultrasound-assisted Fenton process (Sono-Fenton) has emerged as a promising alternative due to its ability to optimize degradation time and increase ROS formation [1]. This study aimed to prepare, characterize, and apply a carbon-based catalyst obtained from coffee grounds and loaded with FeCl3. X-ray diffraction analysis confirmed the deposition of FeCl3 on the carbon support and the infrared data confirmed the presence of peaks characteristic of -OH stretching of alcohols, C=O/aromatic and C=C of aromatic rings. SEM micrographs depicted a porous structure, and EDS data confirmed the uniform distribution of iron along the sample surface. Catalytic tests were performed at room temperature (25°C ± 2) with solutions of methylene blue (MB), rhodamine-B (RhB), and methyl orange (OM) at pH 7, adjusted by using HCl and NaOH 1M. Adding H2O2 marked the beginning of ultrasonic irradiation for all catalytic tests performed. The results demonstrated an impressive efficiency of 95 %, 97 %, and 97% for MB, RhB, and OM within 45 minutes.

Graphitic carbon nitride (g-C3N4) is a conjugated polymer mainly formed by carbon and nitrogen atoms in a graphite-like structure. It is widely used in photocatalytic reactions, such as in lithium batteries, sensors, and pollutant degradation. However, its catalytic potential is limited due to its small surface area, numerous electron pairs, structural gaps and low UV absorption. Heterojunction via π-π interaction with porphyrin-like macromolecules will increase the surface area, creating more active sites for adsorption. Therefore, in this work porphyrins were derived from cardanol, the main constituent of cashew nut shell liquid (CNDL). They are macrocyclic compounds formed by four pyrrolic rings joined by methynic bonds, with substituents in the meso and/or β-pyrrolic positions. Their internal cavity allows the addition of substituents and metal ions, making them good options to act in catalytic reduction reactions. Hybridization of meso-metalloporphyrins with g-C3N4 may be an alternative for more effective conversion of 4-nitrophenol, a nitrophenolic compound found in wastewater harmful to fauna, flora, and human health, into a less toxic compound, 4-aminophenol, through heterogeneous catalysis. This work describes the synthesis and characterization of nanocomposite g-C3N4 hybrid with meso-metalloporphyrin (Pd ZnP) derived from cardanol, with potential application in the heterogeneous catalytic reduction of 4-nitrophenol in aqueous solutions. The materials were characterized by UV-vis, FT-IR, RMN 1H, TGA, SEM, and X-ray techniques. The kinetic study of the 4-nitrophenol reduction reaction showed reduced reaction time, following a first-order model, proving the efficiency of the synthesis and catalytic result of the new hybrid compounds, g-C3N4 /PdP and g-C3N4 /ZnP. Furthermore, the study demonstrated that the hybrid compounds can be reused after recycling, contributing to the use of catalysts from renewable sources, thereby reducing the environmental impact.

GQD/TiO₂ nanocomposite preparation for the incrementof photocatalytic activity in paracetamol degradation

e-mail: diego.gloria@unifesp.br

In recent years, the use of nanoparticles in the degradation of organic pollutants has gained popularity. Among the numerous photocatalytic materials investigated, titanium dioxide (TiO_2) effectively degrades various pollutants, including pharmaceuticals such as paracetamol. However, the use of TiO_2 in photocatalysis has been limited by its inefficiency and short electron lifetime. Graphene quantum dots (GQDs) have shown great potential in enhancing the photocatalytic activity of TiO_2. The aim of this work is the preparation and facile dispersion of GQDs over TiO_2 to obtain a nanocomposite for paracetamol photodegradation [1]. GQDs were obtained by the commercial graphene oxide 1% dispersion (Williamblythe) with 1.2 mL ammonium hydroxide. The mixture was kept at 180°C for 12 h under constant stirring of 600 rpm. Then, the solution was centrifuged, and impregnatated onto titanium dioxide (TiO_2) prepared by sol-gel methods. The paracetamol degradation efficiency of the GQDs/TiO_2 nanocomposite was evaluated under UV-light irradiation (black light with λ=365 nm). The results revealed that the GQDs/TiO_2 nanocomposite showed 70% paracetamol degradation efficiency in 60 minutes, while the TiO_2 had only 50% efficiency in the same period.

In conclusion, the facile dispersion of GQDs over TiO_2 creates a nanocomposite material with superior photocatalytic activity for paracetamol degradation. It can attribute to GQDs capacity to reduce the recombination rate of photogenerated charge carriers. Therefore, this study broadens the application of GQDs/TiO_2 in photocatalysis and provides a potential solution for removing paracetamol from the aqueous solution.

ZnO is a highly researched semiconductor because it has interesting properties and many applications [1]. Thus, the present work presents the development through the green synthesis of zinc oxide (ZnO) nanostructures doped with lanthanum (La) stabilized with 1% of Mangifera Indica (MI) gum aiming at photocatalytic applications. There is little research on the use of MI acting as a stabilizer in the doping of ZnO with rare earths, in addition to the inclusion of natural materials in the synthesis can produce products that are less toxic to the environment. To perform the synthesis, the gum of the MI was first extracted using the exudate. Then the synthesis was performed with 1% MI gum, zinc nitrate and lanthanum nitrate that were heated in constant agitation, then it was dried and calcined. For the structural investigation, X-ray diffraction (XRD) was performed and to observe the efficiency of the nanoparticles in the degradation of dyes, the photocatalytic test with methylene blue was performed. In the XRD it was observed that the method used was efficient in the production of ZnO nanoparticles, both for the pure sample and for the woolly doped. A peak attributed to La was observed in the doped nanoparticle that was related to the formation of La_2O_3[2] because of its concentration, it was also observed a deviation of the position of the peaks of the doped sample in relation to pure, as well as a variation of the average of the crystallite. On the photocatalytic activity of the doped material was observed a degradation of 96% of methylene blue in a time of 90 min on UV radiation.

ACKNOWLEDGEMENTS :

Hydrogen can be used as an alternative to fossil fuels in energy production. Traditionally, H_2 manufacturing is achieved through the combustion of fossil fuels, yet it results in damageto the environment. H_2 is not naturally available in the environment, and electrochemical methods to split molecules that contain it can be applied. Electrocatalysts that possess botha high current density and low overpotential are critical for successful Hydrogen Evolution Reaction (HER) [1]. Noble metals like Pt and Pt-based materials have been widely applied for HER [2]. The costly expensive of Pt has been encouraged scientists to research and develop new electrocatalysts materials. In this work, two sulfides were investigated to allow the HER in acid media, WS_2 and MoS_2. Transparent glasses coated with fluorine-doped tin oxide were cut into 1cm x 2cm and were used as substrate to deposit the layers of each material. A solution with 4:1 proportion of distilled water and ethanol was prepared and mixed with Nafion 5 wt.% binder. Drop casting technique was applied to coat the samples with 10µl of the WS_2 and MoS_2 solutions until the complete dry at room temperature, for twice. Electrochemical analysis was performed in acid media to determine the overpotential level of each electrode. The results showed that at 350mV the WS_2 electrode started the HER [3], exhibiting better result compared to MoS_2 (500mV). To future investigations, characterizations morphology, electrochemical and spectroscopic of these materials will be realized.

e-mail: catiaucker@gmail.com

Heterogeneous photocatalysis is a technique that has been widely used in the degradation of organic pollutants mainly found in effluents from industries [1]. $Nb_2O_5$is a semiconductor material used in several technologies, due to its interesting chemical and physical properties, with good thermal stability and wide bandgap [2]. In photocatalysis, Nb_2O_5has been studied and improved to find greater efficiencies in the degradation of organic dyes [3]. Even though it is a material that presents good results, the idea of impregnating Nb_2O_5in photocatalytic supports can help in greater degradation efficiencies. One of the methods for producing this material is microwave-assisted hydrothermal synthesis. Thus, this work shows the impregnation of Nb_2O_5in loofah sponge through the microwave-assisted hydrothermal synthesis method, to use the material as photocatalytic support in RhodamineB dye degradation processes. The Nb_2O_5impregnated has the characteristic of presentinglow crystallinity of the pseudohexagonal phase, which is predominant for materials not submitted to heat treatment. The SEM images show that there is an impregnation of Nb_2O_5on the surface of the loofah. Preliminary photocatalysis results indicate that the support of vegetable loofah impregnated with Nb_2O_5presents good efficiency of Rhodamine B degradation, being able to degrade 100% of the dye in some minutes of the photocatalytic process.

INFLUENCE OF DIFFERENT ANNEALING TEMPERATURES AND ATMOSPHERE ON THE PROPERTIES OF Bi_2O_3 NANOPARTICLES

e-mail: helen_csouza@outlook.com

The metal oxides of the A_2O_3family are materials used in a wide variety of applications due to their exceptional properties, such as high chemical, mechanical and thermal stability. Among these oxides, bismuth oxide (Bi_2O_3) has attracted the attention of several research groups due to its high technological potential for applications in photocatalytic processes, besides being a material-rich polymorphism that allows several phase-dependent physicochemical properties and technical applications [1-3]. However, the synthesis of Bi_2O_3polymorphs requires expensive and difficult-to-reproduce routes [2]. Thus, in this work, we studied the synthesis of Bi_2O_3nanoparticles using the solvothermal method, in which we sought to evaluate the influence of different annealing conditions on the properties of Bi_2O_3. The precursors used in the synthesis were Bismuth nitrate pentahydrate, ethyl alcohol, and sodium hydroxide. The samples were annealed at room pressure and at 10 mtorr, using the following temperatures: 300°C, 400°C, 500°C, 600°C, 700°C and 800°C. Preliminary characterizations indicate that some samples present a mixture between two phases: the cubic phase of $Bi_2O_3$and the monoclinic phase of Bi_2O_3, which are directly influenced by the calcination temperature.

Influence of the CN-HAp percentage on hidroxyapatite composite synthesized from eggshells for photodegradation of dyes

Amanda Menezes Caldas[1]

[1]Universidade Federal do Rio Grande do Norte (*Engenharia de Materiais*)

e-mail: amanda.caldas.475@ufrn.edu.br

Heterogeneous photocatalysis is a method capable of degrading chemical species, such as dyes, from industrial processes, from the absorption of photons by a semiconductor, where obtaining an efficient photocatalyst can be done from the synthesis of heterostructures, which combine energetically. g-C3N4 is a semiconductor that can be easily synthed from the calcination of urea and other low-cost products. Despite having acceptable bandgap, its rapid recombination of photoinduced electron-hole pairs and low surface area make its application difficult for photocatalysis. On the other hand, hydroxyapatite is a calcium phosphate, which can be extracted from biogenic sources, such as eggshells, but which has a high bandgap value. Thus, the synthesis of heterostructures combining CN-HAp was proposed using the hydrothermal method with microwave irradiation. Hydroxyapatite and g-C3N4 were produced from eggshell and urea calcination, respectively. The photocatalytic performance under sunlight and UV irradiation was evaluated for different dyes, as well as the reuse of photocatalysts, simulating real conditions, which implies a high potential for practical application.

This review describes the applications of HAp compounds and derivatives in the degradation of organic pollutants, with emphasis on the removal of dyes, drugs and pesticides in modification studies and their properties and stability.The fundamentals of heterogeneous photocatalysis were accepted, combined with operational parameters that worked on HAp degradation, strategies and modification functions (doping, catalytic support, heterojunction). Furthermore, emphasizes, discusses and reports the state of the art of these promising compounds for use and insights into their efficiency, ease of synthesis and nature to remove pollutants from wastewater streams, primarily using heterogeneous photocatalysis as an active methodology in wastewater destruction. These compounds are considered to be efficient photocatalysts due to their ease of removing contaminants from wastewater using advantageous redox activity and other flexible properties. The synergistic effect is explained due to structural changes that minimize ecological and environmental problems. According to the knowledge acquired so far, in addition to the numerous applications of HAp in tissue engineering, doped, supported, constructed and heterostructured HAp were found in photodegradation studies. Therefore, considering the rapid advances in technology in the discovery of new compounds, many promising indicators can be applied to raise even more challenges in science and research

The increasing popularity of fullerenes and their derivatives over the past few years is due to the fact that they exhibit interesting properties that include high affinity of electrons and the ability to be excited with high-energy light [1]. Fullerenes have good conductive properties, large specific surface area, high chemical and thermal stability. These features make them attractive for application in variety of areas, like photovoltaic devices, as catalysts in the synthesis of fine chemicals or photodynamic therapy [2].

This work presents a study devoted to fullerene C_{60} derivatives as promising photosensitizers. In order to determine their usefulness, spectroscopic measurements were carried out and their quantum yield of singlet oxygen photogeneration was estimated. Moreover, the results made it possible to evaluate the effect of functionalization of fullerene core on its photosensitizing properties. It has been shown that dyads due to the presence of these thiophene-based lancets are more effective than unsubstituted C_{60}in white light. Selected C_{60}dyads were used as a source of singlet oxygen in a model DHN Photooxidation reaction in a batch photoreactor.

Investigation of Supercapacitor Properties using Iron Tungsten Porous Electrode in aqueous electrolyte

MARIA JOSEITA DOS SANTOS COSTA[1], GILSON DOS SANTOS COSTA[1], REGINALDO DA SILVA SANTOS[2]

[1]Universidade Federal do Piauí (*PPGQ*) , [2]Universidade Estadual do Piauí (*ppgq*)

e-mail: joseita.costa@gmail.com

Porous supercapacitors (SCs) materials are great interesting for energy storage system [1]. This paper, iron tungstate mixed oxides electrode was prepared by polymeric precursor method and deposited onto conductor substrate by drop casting heat-treated at 500 ºC for 2 h. The thermal, structural, and morphological characterization was realized by differential scanning calorimetry (DSC), X-ray diffraction (XRD), emission-scanning electron microscopy (FE-SEM), atomic force microscopy (AFM), respectively. Crystallization process of polymeric resin occurred at 454°C. Synergistic effect of monoclinic FeWO4 and monoclinic Fe2W3O12 phases were confirmed with Fe/W mixed oxides. An irregular shape of condensed spherical-like particles aggregated with rough and porous nanostructures were observed. SC electrochemical analyses of Fe-W electrode accomplishes a capacitance of 75 F g-1 at 5 mV s-1, energy density of 3.73 Wh kg-1, power density of 582.1 W kg-1and long-term electrochemical cycling with a capacity retention of 94.04% after 6000 cycles. Therefore, Fe-W based electrode demonstrates a potential supercapacitor device with excellent stability in a nontoxic aqueous electrolyte.

Lanthanum ferrites synthesized by solution combustion synthesis (SCS) using sucrose as fuel.

Thais dos Santos Haas[1], Vânia Caldas de Sousa[1], Camila Schaefer Konzen[1]

[1]Universidade Federal do Rio Grande do Sul (*Departamento de Materiais - Laboratório de Cerâmicas Avançadas*)

e-mail: haasthais@gmail.com

Abstract Lanthanum ferrites present electrical and magnetic properties that enable their use in several areas. Specifically, strontium and cobalt doped lanthanum ferrites have electrical conductivity and thermal stability, which enable their use, for example, as electrodes in solid oxide fuel cells [1-3]. This study aimed to synthesize $La0,6Sr0,4Co0,8Fe0,2O3$ nanoparticles powders through solution combustion synthesis using sucrose as fuel aiming several applications. The excess of cobalt in the composition provides greater conductivity. The $La0,6Sr0,4Co0,8Fe0,2O3$ powder was obtained using oxidant and reductant reagents in a stoichiometric amount and in excess of reductant reagent in the composition. In sequence, thermal treatment in several temperature ranges was performed. As a result, the samples calcined at 1200°C showed the best structural characteristics in relation to the other temperatures used, but with the largest crystallite size. Also evaluated were the electrical properties. The conductivity of the materials tends to increase with increasing temperature and excess of fuel.

e-mail: luizfernando17@hotmail.com

Macroporous silica/niobium pentoxide composite monoliths were synthesized by sol-gel method. Macroporosity was induced by spinodal decomposition, using PEG 10000 as soluble polymer, triggered by the presence of ammonium niobate(V) oxalate in the precursor solution as described elsewhere [1]. Monoliths were calcinated at 500, 700 and 900 °C Composite structure was characterized by XRD, MEV, HRTEM, N2 adsorption. Macroporous interconnectivity was studied by methylene blue adsorption, after adsorbing the dye for three, six and nine days, the monoliths were cut in half for evaluating the internal surface of the material, the progression of the color towards the center of monoliths showed the interconnectivity of pores. By MEV the macropores are in the range of 1 to 3 μm, by HRTEM crystallite size of niobium pentoxide showed dependance on calcinating temperature, ranging from 4 nm at 500 °C, to 8 ± 2 nm at 700 °C, to 16 ± 6 nm at 900 °C. The d spacingof planes at HRTEM were in accordance with XRD data and at 700 and 900 °C the predominant phase of niobium pentoxide was the orthorhombic. Surface area also showed dependance on calcinating temperature, ranging from 705 m²/g at 500, to 502 m²/g at 700, to 211 at 900 °C. The composite was studied for Doxycycline adsorption at pH range from 2to 12, in all the cases, sample calcinated at 700 °C showed better performance than samplescalcinated at 900 °C and calcinating at 500 °C lead to the lowest adsorption. Maximum ofadsorption at pH 9, in sample calcinated at 700 °C (50 mg/g). This result indicates that forthis type of composite not only the highest surface area maters for great adsorption, structural properties (as crystallite size and zeta potential) are also important.

Membrane scaling in electrodialysis for fluorideremoval from groundwater

Caio Cezar Neves Kunrath[1], Franco Dani Rico Amado[2], Tatiane Benvenuti[2], Andrea Moura Bernardes[1]

[1]Universidade Federal do Rio Grande do Sul, [2]Universidade Estadual de Santa Cruz

e-mail: caiokunratth@gmail.com

This research deals with the natural contamination of groundwater by fluoride(F-) and the application of the electrodialysis(ED) technique to remove F-. Fluoride contamination is a recurring issue all over the world. International health organizations establish 1.5 mgF-/L as the limit in drinkable water. Conventional water treatment is ineffective in removing F-, which makes it necessary to use alternative techniques, such as ED. This process apply ion-selective membranes and electric potential as the driving force to remove F-. During the ED tests, parameters were monitored, including conductivity, F- concentration, potential and current, to evaluate the performance of the process. A synthetic solution simulating natural groundwater containing 5.5 mg/L of F- and other ions that compete with F- transport was treated by ED. The results showed a demineralization of 86.9% with a 0.005σ. However, there was an unexpected behavior regarding the concentration of F- It remained stable in the range of 10 to 11 mg/L after the 4° cycle of concentration. This behavior can be explained by a phenomenon scaling, which is the precipitation of inorganic salts on the membrane surface, and could be intensified by concentration polarization [1]. To confirm this assumption, scanning electronic microscopy(SEM) images for new and post-use anionic membranes were obtained. Magnified 1000x, the SEM images evidenced precipitate on the membrane. The analysis of energy dispersion X-ray spectroscopy obtained coupled to SEM indicated the precipitate composition, including F and Ca for the post-use membrane. A chemical speciation diagram obtained using the Hydra Medusa software had also confirmed the formation of CaF_2. Furthermore the solubility of CaF_2 is 16mg/L[2]. The study indicatedthat ED is an effective technique to remove F-, but there are still challenges to be beat forits large-scale. An alternative is to evaluate the ED reversal, aiming to reduce polarization concentration and scaling.

Microwave-assisted synthesis of Carbon Dots from glycerin residue and its photophysical studies

Carolina Inácio Portela[1], Thais Aline Prado Mendonça[2], Nirton Cristi Silva Vieira[1], Maraísa Gonçalves[1]

[1]Universidade Federal de São Paulo (*Instituto de Ciência e Tecnologia*) , [2]Universidade Federal de São Paulo (*Instituto de Ciência e Tecnologia*)

Carbon Dots (CDs) are nanomaterials smaller than 10 nm with unique electrical and optical properties like tunable photoluminescence, light absorption over a wide range, and higher electrical conductivity. CDs are versatile and can be applied in biomedicine, optoelectronics, sensing, catalysis, etc. Several organic precursors can be used to prepare the CDs, including glycerin. However, glycerin as a by-product in biodiesel production has still not been explored in synthesizing CDs. Glycerin residue can impact the economic and environmental viability of biodiesel, and research for the application of this by-product, particularly in a green and sustainable way, are necessary. In this study, CDs from crude glycerin were prepared by microwave-assisted synthesis and applied as photocatalysts CDs from pure glycerin were also synthesized for comparison. Hexamethylenediamine was used as a dopant in both cases to increase the emission. The synthesis was carried out in a microwave oven (PMM24, Philco) using a power of 504 W and irradiation time of 3 minutes. For the photophysical study, absorbance, fluorescence emission, and excitation measurements were conducted in a spectrofluorometer (FS-5, Edinburgh Instruments). Results showed more considerable emission (at λ_{exc}=380 nm) by CDs from the crude glycerin doped with hexamethylenediamine. These CDs showed one broad emission band with three peaks at 415 nm, 438 nm, and 462 nm. The CDs were impregnated with TiO_2, and the photocatalysis activity was observed in the paracetamol degradation. Thus, we believe that crude glycerin can be used for the production of functional photocatalysts to be used in the remediation of contaminants.

The Borborema Province in the Northeast of Brazil is characterized by the presence of mineral resources such as kaolin. Its processing generates residues rich in kaolinite, mica and quartz, which need to be managed and reused. Therefore, this study aims to add value to these residues by its use in photocatalysis as support materials for TiO_2, a photocatalytic material. The residues were characterized by x-ray diffraction (XRD) and energy dispersive spectroscopy (EDS), and subsequently they were submitted to mechanical agitation and particle size separation. After this process, the $TiO_2$was deposited in the residual quartz by the modified Pechini Method. Titanium citrate was used as a precursor for the synthesis of the polymer resin when reacting with ethylene glycol. The resin underwent a first calcination at 300°C, and subsequently a second calcination was performed at four distinct temperatures (500°C, 600°C, 700°C and 800°C)[1]. The calcined materials were characterized by XRD, ultraviolet-visible spectroscopy and infrared spectroscopy. The formation of anatase and rutile in different proportions depended on temperature, with band gap value varying between 2.6 and 2.9 eV. To attest the photocatalytic efficiency, eachmaterial was tested in a UVC reactor in reaction with terephthalic acid (TA), a probe forhydroxyl radicals. The aliquots were analyzed in a spectrofluorimeter to evaluate the formation of 2-hydroxyterephthalic acid, a fluorescent compound, originated due to the reaction of ●OH with TA [2]. The results of photocatalytic tests attested to a greater formation of ●OH for the synthesized material at a temperature of 600°C, while quartz isinert to photocatalysis.

MoO3 applied in the discoloration of textile dyeaqueous solution

Samuel da Silva Lima[1], Ieda Maria Garcia dos Santos[1], Adervando Sebastião Silva[2]

[1]Universidade Federal da Paraíba (*Química*) , [2]Universidade Federal da Paraíba (*ccen*)*e-mail: sammsilvalimaa23@gmail.com*

The project involves the synthesis of molybdenum trioxide by the microwave-assisted hydrothermal method, with orthorhombic or hexagonal structure, and application in the photocatalytic discoloration of methylene dye in aqueous solution. In the last years MoO3 has been studied for the photodegradation of several dyes, including MB, with good results. In the present work, photocatalytic and adsorptive tests were carried out, and the interaction between molybdenum trioxide and methylene blue was evaluated as well the photohydroxilation of terephthalic acid (TA), used as probe for hydroxyl radicals, to verify if the photocatalytic process really occurs. The tests with MB were performed using the dye in solution at three different values of pH, 4, 5.6 and 8, as the solution pH determines the amount of the protonated dye molecules and consequently the interaction between dye and substrate. Very good results were obtained at pH 4 with values above 90% for discoloration for adsorption or photocatalysis after 8 h of test, for both MoO3 phases, whereas the orthorhombic phase showed a faster reaction kinetics compared to the h-MoO3. Nonetheless, the h-MoO3 showed good values of discoloration for photocatalysis in pH 8 after 8 h, with a growth of approximately 5-fold comparing to adsorption. For all samples photodegradation takes place, but the discoloration occurs by a direct photocatalytic process, in other words, the photocatalytic process occurs due to direct electron transfer between dye and MoO3 without the formation of hydroxyl radicals, as indicated by the small amount of hydroxyl radicals in solution in the presence of MoO3 indicated by the photohydroxilation of TA under UVC irradiation.

e-mail: willians.almeida@ifap.edu.br

The aim of this work was to investigate the influence that starches from different botanical sources have on some properties of zinc oxide synthesized by the starch-assisted sol-gel route [1]. In this sense, three ZnO powders were synthesized so that cassava, potato and corn starches were used in the synthesis as stabilizing agents for the formation of nanoparticles. In general, it was observed that the type of starch has a certain influence on the crystallite size, as well as on the band gap value. The smallest crystallite size (20 nm), calculated by the Scherrer formula, was found in ZnO whose starch used in the synthesis was cassava, as well as the largest band gap (3.16 eV), calculated by the tauc method, was obtained for this same sample. Based on literature values, cassava, potato and corn starches have amylose contents of 17%, 21% and 26% respectively [2]. From this, it was noticed that when using starch with a lower amylose content, we obtained a ZnO with a smaller crystallite size and a higher band gap value.

e-mail: guirizzomatias@hotmail.com

$Ni_{0.3}Cu_{0.2}Zn_{0.5}Fe_2O_4$ ferrite was evaluated as photocatalyst in the degradation performance of industrial effluent methylene blue (MB) using solar photocatalysis. Ceramic materials can be a promising field of research extremely attractive in renewable energy and with great industrial possibilities. The photocatalyst was produced by combustion reaction, a method chosen for presenting a low energy consumption, being fast to manufacture [1]. The experiment was done using Ni-Zn ferrite doped with 2% Cu ions ($Ni_{0.3}Cu_{0.2}Zn_{0.5}Fe_2O_4$) [2]. The best conditions of the variables during the solar heterogeneous photocatalysis process were 10 mg/L of MB, 2.0 g/L of photocatalyst, 408 mg/L of H_2O_2 and pH 3. The photocatalyst studied combinated to such parameters reached an efficiency of 79.3%, in terms of color removal and dye concentration, demonstrating to be an efficient photocatalysts for degradation of MB. A deeper statistical planning, in order to determine the best conditions of the variables studied and to find the optimal point for degradation of the MB dye will be developed.

Obtaining dense $Ba_5Nb_4O_{15}$ ceramics at lower sintering temperatures

Kethlinn Ramos[1], Karolyne Juchok Carvalho[2], Adilson Luiz Chinelatto[3], Adriana Scoton Antonio Chinelatto[3]

[1]Universidade Estadual de Ponta Grossa (*Programa de Pós-Graduação em Engenharia e Ciência de Materiais*) , [2]Universidade Estadual de Ponta Grossa (*Departamento de Engenharia de Materiais*) , [3]Universidade Estadual de Ponta Grossa (*Departamento de Engenharia de Materiais / Programa de Pós-Graduação em Engenharia e Ciência de Materiais*)

e-mail: kethlinnramos@gmail.com

$Ba_5Nb_4O_{15}$(BNO) ceramics have been extensively investigated for their dielectric and luminescence properties. Furthermore, this material displays protonic conduction and has potential to be used as electrolyte in solid oxide fuel cells (SOFCs) [1]. SOFCs are important devices in changing the energy matrix. However, producing dense BNO ceramics for use as electrolytes in SOFCs presents difficulties, since high sintering temperatures can result to elongated grain growth and even de-sintering phenomena [2]. Therefore, in this work, it was employed the solid-state reaction synthesis with successive milling and calcination steps. This synthesis process already allowed an increase in densities at lower sintering temperatures. The sintering conditions used included the conventional method using sintering aids, as well two-step sintering of pristine BNO. The X-ray diffraction patterns of calcined powders revealed a single phase of $Ba_5Nb_4O_{15}$. The samples sintered using sintering aid, 1-3 wt.% ZnO, achieved satisfactory densification of 95% at a sintering temperature of 1200 ºC, but SEM images revealed abnormal grain growth. On the other hand, the samples with NiO resulted in sample with elevated porosity. For two-step sintering, the first step temperature was 1250ºC, and both second step conditions, at 1200 and 1150ºC, achieved densities of 92%. However, when the second step is 1150ºC, a more refined microstructureis obtained.

e-mail: vsmarques7@gmail.com

The technological advances have increasingly and the preparation of materials with unique properties is required to meet functional needs. In this work, powders of $Ag_2WO_4$and Ag_2MoO_4, which were previously synthesized by the co-precipitation method, were incorporated at 50 wt-% into the matrix of poly(vinyl alcohol) (PVA) (conc. 10 wt-%) for preparation of composite ceramic nanofibers, using the electrospinning method. The obtained materials were structurally characterized by DRX, and the morphology was evaluated by SEM, for further studies of photocatalytic and antimicrobial properties. DRX profiles of $Ag_2WO_4$and Ag_2MoO_4powders indicate the prevalence of β-$Ag_2MoO_4$and α-Ag_2WO_4phases, respectively, and that the peaks remain very sharp in DRX of PVA/$Ag_2MoO_4$and PVA/Ag_2WO_4composite nanofibers. SEM images show that powders and electrospun nanofibers possess non-uniform distribution. Electrospinning was effective in the preparation of PVA/$Ag_2MoO_4$and PVA/Ag_2WO_4fibers. Antimicrobial and photocatalytic activities essays are ongoing. Antimicrobial activities of powders and polymeric mants against Pseudomonas aeruginosa and Staphylococcus aureus were investigated through the minimum inhibitory concentration (MIC) and the minimum bactericidal concentration (MBC) [2]. The results indicate that the materials have strong antimicrobial potential of action.

The conversion of solar energy into chemical energy via photoelectrocatalysis is considereda promising alternative in the face of the current energy crisis.[1] We report the synthesisvia electrochemical anodization of TiO2 nanotubes with graphene oxide and in situ reduction by thermal route in an oxidizing and inert atmosphere (N2 controlled flow).[2] We investigated the effect of thermal reduction of graphene oxide (GO) on the photoelectrocatalytic properties of the TiO2/rGO composite in order to improve light absorption. The photoanodes produced were characterized by Raman Spectroscopy and SEM, in addition to their photoelectrochemical evaluation. The TiO2 photoanodes showed a photocurrent density of 0.075 mA.cm-2 and resistance of 5.93 kΩ in anatase phase. TiO2/rGO treated in an ambient and inert atmosphere has a photocurrent density of 0.135 and 0.480 mA.cm-2, 1.8 and 5.4 times greater than pure TiO2, respectively. A system resistance reduction was also observed for both systems, going to 3.7 kΩ after heat treatment in an inert atmosphere. The heat treatment atmosphere interferes with the quality of the photoanodes produced, due to the difference in the degree of reduction of the GO structures anchored in the nanotubes. This behavior is evidenced in Raman spectroscopy, where a reduction in the degree of structural disorder is shown after thermal treatment in an inert atmosphere, reinforcing the hypothesis of GO conversion into rGO.[3] These results suggest that treatment in an inert atmosphere promotes a more efficient reduction of GO directly in the TiO2 nanotubular matrix, restoring the typical structure of graphene and, consequently, improving the photoelectrochemical performance.

Water quality is a pressing issue for present and future generations, highlighted by the UN''s 2030 Agenda for Sustainable Development [1]. In Brazil''s northeast, textile industries are a major source of water contamination due to recalcitrant dyes, exacerbating the limited water supply. Improved technologies are necessary for enhanced efficiency of water treatment systems. Advanced oxidation processes (AOPs) like photocatalysis hold promise for effective treatment, but commonly used semiconductors like TiO_2have limited responseto visible and sunlight, necessitating modifications for effective operation. To obtain a nanostructured material based on Ni@TiO_2nanotubes, this study optimized pulsed anodization [2-3] parameters (potential and deposition time) using the design of experiments (DoE). A two-electrode system was used, with a titanium foil and copper plate as anode and cathode respectively, connected to a sourcemeter model 2400 (Keithley) and controlled by Labview (National Instruments). The electrodes were fixed at 1 cm and immersed in an electrolyte solution (0.7% ammonium fluoride (NH4F) with 100 mM of Ni^{2+}dissolved in 90:10 v/v mono ethylene glycol:water) under stirring (200 rpm). Anodization parameters were fixed at 30 V for 5 s followed by deposition conditions. Photocurrent density (mA/cm2) and methylene blue photodegradation (%) were evaluated as responses during the DoE and reported significant effects of both deposition parameters. **Acknowledgements**: This work was supported by FNDCT through Finep [process 0122056900] and by Facepe [APQ-1237-1.06/21]. PCS is grateful to Facepe for her scholarship [BIC-0248-3.07/22]. VNL, CEML and BRSI are grateful to CNPq for their PCI fellowship and PhD scholarship [process 140123/2022-9]. **References**: [1] UN, The 2030 Agenda for Sustainable Development. [2] T. Soares, T. e-mail: ludmila-aragao@hotmail.com

Recently, new photocatalytic materials, such as doped and heterostructured materials, have been studied, as these systems have great potential for the development of heterogeneous photocatalysis powered by solar energy for environmental remediation [1]. Heterogeneous solar photocatalysis has received increasing attention for presenting important environmental applications, being an efficient technology in the degradation of pollutants in water and synthetic dyes from textile dyeing. The objective of the study was to use modeling and optimization to statistically analyze the demineralization of textile effluent with methylene blue dye (MB), using NiZnCuFe nanoferrite as a semiconductor photocatalyst (dopping of 30% Cu) and solar energy as an energy source. For this, a full factorial experimental arrangement with three input variables (2k = 23) and insertion of center points based on Response Surface Methodology (RSM) was used. The response variables fitted well to the evaluated tests, obtaining significance in the parameters related to pH and hydrogen peroxide concentration. It was found that the optimal values for the photocatalyst would be 0.1 g/L; hydrogen peroxide 120 mg/L and pH at 5, in which under these conditions a maximum yield of 73.83% of degradation of the MB dye was reached.

Permeable concrete with ZnO nanoparticles applied tothe treatment of industrial effluents

e-mail: g.tolosa@unesp.br

Emerging contaminants (ECs) from inappropriate industrial disposal, are a constant concern today, due to its tendency to degrade the aquatic environment and cause a serious threat to living organisms. Nowadays, dyes are present as one of the main alarming sources of water contamination from the industry. Studies on the photodegradation of contaminants in wastewater using nanomaterials have stood out as an environmentally correct process that completely destroys pollutants [1,2]. Combining this property in the industrial structure has been a challenge for engineers and scientists. Permeable concrete (PC) is a material composed of an abundant volume of interconnected pores, allowing water to pass freely through the brick. As result, new technologies are being applied to this concrete to improve the quality of the water that passes through and reaches the ground, as well as treatment that allows the PC to act in the decontamination of water [3]. In this work, permeable concrete bricks with controlled porosity will be produced and subsequently impregnated with zinc oxide nanoparticles (ZnONPs) with photocatalytic properties synthed by hydrothermal method for the treatment of effluents. The concentration of dye; dosage of nanoparticle; pH effect, and contact time were evaluated using only ZnONPs. The methylene blue dye (MB) photodegradation under UV-Vis light reached 73% at pH 6 and 92% at pH 10, with 10 mg of nanoparticle and a dye concentration of 10 mg/L.

Permeable Reactive Barrier for soil remediation using Sodium Polyacrylate

Alana Maria Corá[1], Maira de Lourdes Rezende[2], Silvia Pierre Irazusta[1] [1]Faculdade de Tecnologia de Sorocaba (***Laboratório de Toxicologia Ambiental e Ocupacional***) ,
[2]Faculdade de Tecnologia de Sorocaba (***Polímeros***)

e-mail: alana.cora@fatec.sp.gov.br

The growing contamination of ecosystems from industrial activities is a problem to be solved by organizations and society. Despite state and federal laws, the incorrect disposal of contaminated waste in soils and watercourses continues to be a habit and, over the years, the consequence is the formation of environmental liabilities, especially in industrial areas [1]. The present work aimed to establish a method for remediation of soils contaminated with toxic metals, using a permeable reactive barrier (PRB) [2]. To demonstrate the effectiveness of sodium polyacrylate (PAAS) in the adsorption of the contaminating metals, a leaching test was carried out. For this, the samples were mounted vertically in 1.5L PET bottles with layers of contaminated soil, polymer and standard soil. The layer of ''swollen'' or original powdered sodium polyacrylate was placed between the two soils to act as a barrier. The system was kept for 30 days and disassembled for further analysis using Inductively Coupled Plasma (ICP) to detect metallic elements. The results showed a reduction in the levels of Ba (42.87%), Pb (70.37%) and Fe (48.63%) in the contaminated soil, by transferring it to the PAAS, where the metals were retained. The highest transfer and adsorption occurred in the assembled system with the polymer in powder form. In this way, the PAAS proved to be efficient in the removal of contaminating metals from the soil, such as a PRB, at least for those analyzed. The resulting polymer residue could be used in the cement industry, in line with circular economy principles.

Photocatalytic activity of Nb-doped TiO_2 thin films deposited by spin coating

Diego Alexandre Duarte[1], Augusto Amancio dos Santos[1], Rafael Gallina Delatorre[1]

[1]Universidade Federal de Santa Catarina (*Engenharias da Mobilidade*)

e-mail: diego.duarte@ufsc.br

Since the discovery of the high electrical conductivity of Nb-doped TiO_2films [1], investigations of this material have been addressed toward applications as transparent conducting oxides [2] and thermoelectricity [3]. In this work, the catalytic activity of Nb-doped TiO_2thin films from degradation of methylene blue (MB) is investigated. Films composed by $TiO_2$and Nb_2O_3nanoparticles were deposited on polished aluminum substrates by spin coating as function of the Nb_2O_3concentration (0, 2.5 and 5.0% wt.). Experiments of the catalytic activity were carried out in a homemade experiment composed by a ramp where the MB particles, dissolved in deionized water, flow over the substrate surface with controlled speed under UV irradiation. The optical properties of the tested solutions, such as absorbance and degradation efficiency, were evaluated by UV-Vis spectroscopy as a function of the degradation time. Samples were also analyzed by X-ray diffraction, field emission scanning electron microscopy, X-ray photoelectron spectroscopy and four-point probe to investigate the crystalline structure, morphology, chemical composition and electrical properties, respectively. Films are polycrystalline with preferential anatase phase, 30 μm average particle size with homogenous distribution, no structural failures, low Nbconcentration and influence of the Nb content on the MB degradation.

e-mail: adervando20@hotmail.com

The mitigation of pollutants in general has become one of the most challenging and critical tasks for the entire scientific community [1]. In this context, this work aims to obtain materials with $SrSnO_3$structures superficially modified with $Ag^+$and formic acid for the evaluation of photocatalytic performance by the photohydroxylation of terephthalic acid. The $SrSnO_3$was obtained by the method of modified-Pechini method, with calcination at 900°C, while the solid $SrSnO_3$/Ag was obtained by photodeposition of Ag under UVC radiation and drying for 24 hours at 80°C. The obtained powders were characterized by X-ray diffraction (XRD), infrared spectroscopy (IR), ultraviolet-visible spectroscopy (UV-vis), field-emission scanning electron microscopy (FE-SEM) coupled to energy dispersion X-ray spectrometry (EDS). The photocatalytic applications suggest a satisfactory performance in the photohydroxylation of terephthalic acid by both systems mentioned above, with emphasis on the $SrSnO_3$/Ag system. The use of scavengers such as isopropanol, EDTA, and N_2revealed in more detail the oxidative species responsible for the photocatalytic performance both for the $SrSnO_3$system and for the $SrSnO_3$@Ag composite, as well as the possible photocatalytic pathways that followed the photohydroxylation reactions and generation of the fluorescent compound 2-hydroxy-terephthalic acid, which was monitored by spectrofluorimetry.

Organic pollutants, such as dyes, have been discharged into the environment by the industrial sector, with negative impacts on water resources and ultimately, posing risks to the human health.(1) Photocatalysis presents a viable solution to this problem by effectively converting solar energy into chemical energy, thereby facilitating reactions that contribute in the removal of these contaminants from water resources.(2) Metal-organic frameworks (MOFs) are 3D porous structures that have been recently explored in photocatalytic applications, as well as modified MOFs, to enhance the effect of photocatalysis.(3) Here we synthesized MOF MIL88A and MIL88A/Molybdenum disulfide (MoS2) composite to compare their efficiency and investigate the formed heterojunction in photocatalytic activity. Subsequently, to facilitate the recovery of the catalyst, the particulate was immobilized on C/SiO2 ceramic fibers obtained via the solution blow spinning (SBS) method. The morphological aspects of MOF/MoS2 supported on C/SiO2 were determined by scanning electron microscopy (SEM) techniques. The crystalline and chemical structures were determined by X-ray diffraction (XRD) and infrared spectroscopy (FTIR), respectively. The materials' photocatalytic activity was investigated towards methylene blue (MB) and rhodamine B (RhB) solutions as model dyes using UV-Vis spectroscopy. The catalytic activity of the MOF was tested in solutions of MB and RhB, achieving efficiencies of 48.5% and 58.92%, respectively, while the MOF/MoS2 exhibited superior performance with efficiencies of 90.04% and 71.73%. The ceramic fibers C/SiO/MOF/MoS2 yielded results of 37.25% for MB and 24.59% for RhB. Acknowledgments: the authors thank to CAPES, CNPq, FAPESP and Embrapa. References: (1) Jeong C. et al. CeO2 is considered a photocatalyst that has a higher degree of crystallinity and larger lateral s, therefore a smaller specific surface area and a lower concentration of oxygen vacancy on the surface [1]. Although this oxide shows photocatalytic activity in the degradation of organic pollutants, certain aspects of CeO2, such as the high recombination rate of electron-hole pairs[2]. To overcome these drawbacks, heterostructures based on clay minerals, such as palygorskite, have been widely used for the removal of various organic pollutants due to their excellent adsorption capacity [2]. The present work is focused on the development of CeO2 nanocubes (CeO2-NC) and its respective hybrid material CeO2-NC/Paly based on the combination of CeO2-NC and palygorskite fibrous clay. These materials were characterized by diverse physicochemical techniques, such as XRD, FTIR, N2 adsorption (BET analysis). To evaluate the photocatalytic activity of the hybrid material, these materials were used employing the CIP antibiotic drug as a contaminant model, and the mechanism of the degradation process was evaluated using the diverse scavenges of the oxide-reduction reaction. The physicochemical characterization pointed out that the structure of CeO2-NC in CeO2-NC /Paly was preserved. The photocatalytic tests showed a total degradation of around 93%, while the isolated semiconductor showed around 60% of ciprofloxacin degradation, indicating that the photocatalytic activity of the CeO2-NC material was improved with the presence of Paly.

e-mail: dellacosta.ml@gmail.com

The contamination of the environment by toxic elements due to the increasing anthropic action directly affects the environmental balance. Synthesis and characterization of Fe_3O_4, ZnO and TiO_2[1,2], and nanocomposites system ZnO−$Fe_3O_4$and TiO2−Fe_3O_4 and realized comparative study between photocatalytic processes for Rh B removal were carried out. The nanoparticles were characterized for X-Ray Diffraction (XDR), Scanning Electron Microscope (SEM), Fourier-transform Infrared Spectroscopy (FTIR), Zeta Potential (ZP) and Ultraviolet-visible Spectroscopy (UV-Vis). Results indicate that between photodegradation and photo-Fenton assays there was a variation rate of removal 7.5 to 100% for nanomaterials studed. The presence of light in the Fenton process is favorable to the degradation reaction for magnetic materials, since it is attributed to the reduction of Fe^{3+} to Fe^{2+}, a species that reacts directly with H_2O_2 favoring the Fenton process with formation of hydroxyl radicals, showing an expressive improvement, which is directly related to Fe_3O_4. This theme is current and of great relevance to the synthesis of catalytic materials and environmental issues.

Photodegradation of the drug hydroxychloroquineusing copper-silver titanatenanotubes

EMANUEL DA CRUZ LIMA[1], José Milton Elias de Matos[1], Jardel Meneses Rocha[2], Ezequiel da Cruz Lima[3]

[1]Universidade Federal do Piauí (*PPGCM*) , [2]Universidade Federal do Piauí (*PPGQ*) , [3]Instituto Federal de Educação, Ciência e Tecnologia do Piauí (*PPGCM*)

e-mail: emanuel.lima@ifma.edu.br

Hydroxychloroquine (HCQ) belongs to the group of 4-aminoquinolines and is used as an antimalarial medication in treating rheumatological and dermatological diseases [1]. In early 2020, during the Covid-19 pandemic, even though it proved to be ineffective against the SARS-COv-2 virus, it was prescribed by medical organizations for the treatment of coronavirus patients [2]. As a result, it has become an organic pollutant in aquatic environments. Photodegradation using titanate nanotubes (TNTs) sensitized with metal ions has become a promising alternative for the remediation of these pollutants. The present research synthesized titanate nanotubes (TNTs) by the alkaline hydrothermal method, then proceeded with ion exchange with $Ag^+$and Cu^{2+}ions to form the Ag_1Cu_{x-1}TNT nanocomposite for application in the photodegradation of HCQ. The prepared materials were characterized by XRD, MET, BET and DRS. The results indicate that $Ag^+$and Cu^{2+}ions are decorating the surface (as Ag and Cu or CuO) and in the interlamellar spaces (as $Ag^+$and Cu^{2+}) of TiO6. In the photodegradation of hydroxychloroquine, the results show that 5.10^{-3}g of the Ag_1 Cu_{x-1} TNT catalyst reaching 81.16% of photodegradation efficiency in a hydroxychloroquine solution of 5.10^{-3}g/L in 120 min under UV-vis radiation. Thus, the Ag_1Cu_{x-1}TNT catalyst is a potential candidate for removing organic pollutants in aqueous solutions.

e-mail: silvania.lanfredi@unesp.br

The photoelectrocatalytic oxygen evolution reaction was studied under visible-light irradiated W-doped niobate-based perovskites. Nanostructured K0.5Na0.5(WxNb1-x)O3 materials were prepared by ultrasonic spray pyrolysis as a function of 1 - 3 mol% W6+ cations within the host structure. A careful characterization of solids including morphology, structure, texture, optical, and electrochemical properties was performed. HRTEM, ED, and XRD characterization showed the KNN structure is distorted by tungsten doping on corner-shared NbO6. XRD analysis showed an expansion of the KNN unit cell due to the difference in ionic radii between Nb5+ and W6+. To the best of our knowledge, the present W-doped niobate-based perovskites showed the highest turnover frequency reported in the photoelectrocatalytic OER under similar overpotential conditions. From the TOF data obtained for the OER, it can be concluded the present W-doped Niobate-based perovskites showed the highest TOF (84.6 s-1) reported up to now for this reaction under visible light irradiation and using similar overpotential conditions. Overall, the present study strengthens the eco-friendly synthesis conditions by ultrasonic spray pyrolysis, being highly favorable as compared to traditional synthesis routes such as high-energy ball-milling [1] and sol-gel [2]. Accordingly, this new class of perovskite-based crystalline materials opens a door for the scaling-up of catalytic and photocatalytic processes related to energy production.

e-mail: ajaranda@uni.pe

Using electrochemical (chronoamperometry and cyclic voltammetry) and hydrothermal techniques, $CuBi_2O_4/Cu_2O$ films supported on FTO (fluorine-doped tin oxide) conductive glass were synthesized. The first part is the electrodeposition of a layer of Bi_2Se_3, to form $Bi_2O_3$by heat treatment, then a layer of metallic copper is electrodeposited to transform the structure by applying a temperature of 600 ºC and form $CuBi_2O_4$-CuO, later a layer of $Cu_2O$is electrodeposited on the surface in a basic medium[1] to form $CuBi_2O_4/Cu_2O$ (seeds) and finally it is made a hydrothermal treatment to form the $CuBi_2O_4/Cu_2O$ films. The CO2 reduction was carried out in aqueous solution of Na_2SO_4, $NaHCO_3$, $NaHCO_3/Na_2CO_3$buffer and CH_3COONa as supporting electrolytes, using previously synthesized films as working electrode, Ag/AgCl reference electrode and DSA (dimensionally stable anode) counter electrode. A hermetic sealed reactor (1 atm pressure) was used, which had a quartz window for the passage of light.Work was carried out with different pH (4.15, 7 and 10), the applied potential was also varied (0.0 V, -0.2V and -0.4V) and different electrodes (different charges (Coulumb) of electrodeposition of bismuth) obtaining that the best stability of the material and concentration of methanol obtained (using Gas chromatography for its detection) is at pH 4.15 , potential of 0.0 V and an electrolyte solution of sodium sulfate. research was also carried out to obtain a new product from the reaction of sodium acetate and $CO_2$for the formation of methyl acetate (CH_3COOCH_3), determining the new product obtained from a GC-MS, the variation of potential and pH to obtain a better production of this material, obtaining an improvement at pH 5 and potential of 0.0 V .

Preparation of activated carbon/TiO_2 hybrid materialfor sulfamethazine photodegradation

Thais Aline Prado Mendonça[1], Carolina Inácio Portela[2], Nirton Cristi Silva Vieira[2], Maraisa Goncalves[2]

[1]Universidade Federal de São Paulo (*Instituto de Ciência e Tecnologia*) , [2]Universidade Federal de São Paulo

e-mail: thais.mendonca@unifesp.br

Water contamination with emergent contaminants is a serious issue that can devastate the environment and public health. Thus, developing new and efficient materials for eliminating pollutants is necessary. Activated carbon (AC)/TiO_2, also known as hybrid material, is a compound used in photocatalysis applications to degrade emergent contaminants. Both activated carbon and $TiO_2$are cost-effective, green technologies that can be used to remove pollutants from the environment. This work proposes to obtain activated carbon (AC) with high porosity from crude glycerin by activation with $CaCl_2$as activating agent at 0,005 % to 1% of Calcium (% in relation to polymerized glycerin). The produced AC from crude glycerin and commercial AC are used as substrates for preparing photocatalysts with the impregnating a thin film of a semiconductor, TiO_2, to obtain a synergy effect between the adsorption capacity of AC and the photocatalyst efficiency of TiO_2. The proportion AC/$TiO_2$was a variety (10 e 90) % to specify the material''s efficiency. The specific surface area (S_{BET}) found for AC/90$TiO_2$was 120 $m^2.g^{-1}$. The SEM-EDS micrographs of the materials revealed the existence of carbon, oxygen, and titanium on the surface. The XRD and Raman spectroscopy characterization showed the anatase phase corresponding to the TiO_2dispersed and amorphous phase of AC. The efficiency of materials was evaluated in the photocatalysis of organic contaminants, using sulfamethazine (10 ppm) as a model compound. The results showed the total remotion at 240 min by AC-90TiO_2. In preliminary tests for the AC from glycerin (Gli/0,5%Ca), high adsorption of the sulfamethazine was obtained, about 40%. Thus the preparation of hybrid materials showed efficiency in the organic contaminants remediation by synergetic effects of adsorption and photocatalysis. AcknowledgmentsThis work was supported by CAPES and FAPESP (2019/13471-8).

Probing the Iodine to Bromide phase Photoconversionin Colloidal Thin Film of CsPbBrxI(3-x) nanocrystals

Perovskite nanocrystals (ABX3) are extremely promising for applications in solar cells, LEDs, photocatalysts, humidity and temperature sensors, memory devices, and low-cost photodetectors. Such characteristics are due to the high fluorescence quantum efficiency allied to the ionic conduction of the charge carriers. However, photoexcitation triggers the ionic diffusion mechanisms and the energy transfer between nanocrystals (NCs), which are poorly understood. [1,2] Thus, halide perovskite NCs with different chemical compositions have been proposed from a theoretical and experimental point of view. Herein, we used hyperspectral fluorescence microspectroscopy to further our understanding of a few optical phenomena in CsPbBrxI(3-x) thin films. We show that CsPbBr2I, CsPbBr1.5I1.5 and CsPbBrI2 nanocrystals thin films samples exhibited conversion from iodide to bromide phases. Initially, the iodide phase undergoes an abrupt drop until stabilization, while the bromide phase begins a significant growth, surpassing the initial fluorescence intensity presented by the iodide phase. We spatially mapped the fluorescence photoconversion and determined their microscale length. A theoretical model was proposed to explain the results.

Production of pure phase mayenite ($Ca_{12}Al_{14}O_{33}$) powders by solution combustion synthesis by varyingfuel and calcination temperature

Willians Lopes de Almeida[1], Felipe Antonio Lucca Sánchez[2], Vânia Caldas de Sousa[3]

[1]Instituto Federal de Educação, Ciência e Tecnologia do Amapá, [2]Universidade Federal doRio Grande do Sul (*Materiais*) , [3]Universidade Federal do Rio Grande do Sul (*DEMAT*)

e-mail: willians.almeida@ifap.edu.br

This work presents the influence of fuel and calcination temperature to obtain mayenite by solution combustion synthesis (SCS). This is material has characteristics that enable its application as electrochemical components of solid oxide fuel cells, hydrogen storage, cement hydration, among others [1]. All fuels (citric acid, glycine, urea and sucrose) favoured the formation of mayenite, however, only the sample synthesized with glycine (caG) showed 100% of this phase at all three calcination temperatures investigated (1100, 1200 and 1300°C). For the other samples, heat treatment at higher temperatures proves tobe fundamental to obtain the pure mayenite, except for the sample synthesized with urea. Regardless of the fuel used in the synthesis and the phase obtained, the crystallite size, calculated by the Scherrer equation, is smaller than 100 nm, but the caG sample kept the crystallite value (~41 nm) practically unchanged after increasing the calcination temperature. Due to glycine based SCS proved to be more efficient, other analyses were performed only for these powders. From Raman spectroscopy, vibrational structures related to the mayenite phase were identified, which are in agreement with the XRD data for all calcination temperatures. The specific surface area decreased ~19% and laser granulometry analysis revealed an increase of ~4% in the average particle size of this sample (caG) with increasing calcination temperature. Based on the results of this study, it can be concluded that the type of fuel has an influence on obtaining pure mayenite, as well as the calcination temperature and glycine is the fuel that made possible to obtain pure mayenite at 1100°C, that is, at the lowest temperature among those studied.

Photocatalytic heterojunctions obtained from the use of titanium dioxide (TiO_2) and carbon-based materials are a promising way for the efficient water treatment [1]. The structural properties of the composite photocatalysts are an important characteristic that can influence their photocatalytic behavior [2]. Here, TiO_2/expanded graphite (TiO_2-EG) films were synthetized by sol-gel and deposited on borosilicate glass substrates by airbrush spray coating method at room temperature. Then, the hybrid films were heat treated at 350, 450 and 550 °C. Raman spectroscopy technique was applied to evaluate the effect of carbon amount and temperature on the structural properties of the films. The films heat treated at 350 °C exhibited a characteristic profile of amorphous material. Raman spectra of composite films heat treated at 450 and 550 °C showed well-defined peaks that can be attributed to anatase-TiO_2phase. No peaks related to the rutile or other phases were observed. The investigation revealed that the G and 2D bands present a slight shift, as well as asymmetry, as the carbon content and heat treatment temperature increase - behavior that may be associated with the formation of the semiconductor-C heterojunction. Peaks deconvolution process demonstrated the presence of a second signal not found in the pure films. This effect may indicate a reduction of sp^2domains after the formation of semiconductor-C heterojunction, mainly due to the removal of oxygenated groups during heat treatment, and consequent Ti-C / Ti-O-C bonds formation [3]. The results suggested that the carbon amount and the temperature of heat treatment have great influence on the TiO_2 -EG structural properties, which may contribute to the improvement of the photocatalytic activity of the composite films under visible light.

e-mail: m.meirelles@unifesp.br

In this work, activated carbons (ACs) were prepared from lignocellulosic residues and used as support for photocatalyst impregnation titanium dioxide (TiO_2). Besides, the efficiency of this material was evaluated in the photodegradation of organic contaminants investigated. AC''s were prepared using the coffee husks, coffee grounds, and sugar cane bagasse as precursors and phosphoric acid as activating agents. $TiO_2$was prepared by the sol-gel method, with hydrogen peroxide (H_2O_2) and without H_2O_2during the synthesis. Then, all the materials obtained were calcined at 350 and 450 °C for 2 h with a synthetic air flow of 100 $mL.min^{-1}$. The materials were characterized according to their physicochemical properties using different techniques. The results obtained from nitrogen adsorption/desorption verified that the specific surface area (S_{BET}) for all prepared AC''s was similar to or higher than the commercial (1000 $m^2.g^{-1}$). The values found were 990, 1344, and 1465 $m^2.g^{-1}$for AC prepared from coffee husks, sugarcane bagasse, and coffee grounds, respectively. X-ray diffractometry (XRD) analysis verified that all TiO_2samples showed peaks referring to the anatase phase. Furthermore, the photocatalytic efficiency of materials was evaluated in the degradation of the contaminant Acetaminophen (Paracetamol) in the aqueous medium. The results showed that TiO_2prepared in the presence of H_2O_2has greater photocatalytic efficiency, removing approximately 94.3% of paracetamol after 300 min. The different TiO_2samples have been impregnated in the AC with the highest surface area (coffee grounds) using a proportion of 15% TiO_2(w/w). The formed composite will be evaluated in the degradation of Acetaminophen.

Role of Tungsten in the Structure and Photoactivity of Alkali Niobates

Fabiano Rafael Praxedes[1], Marcos Augusto Lima Nobre[2], Juan Matos[3], Silvania Lanfredi[4]

e-mail: fabianopraxedes@gmail.com

Sodium-potassium niobate has been considered a promising eco-friendly ferroelectric material alternative to lead-based compounds [1]. On the other hand, its application in Advanced Oxidative Processes, especially those concerned the photocatalytic reaction, just gained focus recently [2,3]. This work investigated the structure and photoactivity contributions of tungsten doping into the B-site of the $Na_{0.5}K_{0.5}NbO_3$. Nanostructured hollow spheres of $Na_{0.5}K_{0.5}(W_xNb_{1-x})O_3$, where x= 0.01; 0.02; and 0.03 mol% W, were obtained by spray pyrolysis. The powders were produced using a precursor solution (50 mmol/L), which was nebulized at 1.7 MHz and injected by air pumped at 5 L/min into the pyrolytic chamber at 973.15 K. Morphological and structural analysis by Transmission Electron Microscopy and X-ray Diffraction, respectively, confirmed the obtention of the hollow spheres and the perovskite structure. Chemical bonds, band gap energy, and BET surface area were obtained by Infrared spectroscopy, UV-Vis spectroscopy, and N_2-physisorption, respectively. The photoactivity of W-doped KNN was evaluated by means of Basic Blue 41 dye (1L, 26 μmol/L) degradation under UV (7 W, 254 nm) irradiation. The more niobium was displaced by W-doped, the more the photoactivity of the KNN-based materials. The photoactivity increased by up to 14%. The structure and photoactivity of KNN and their relation with tungsten doping are discussed.

TiO2 structures were synthesized by the sol-gel method using Karaya Gum (GKT), having their structure characterized by X-ray diffraction (XRD), scanning electron microscopy (SEM), energy dispersive X-rays (EDS), infrared spectroscopy by Fourier transform (FTIR) and diffuse reflectance and surface area identified by the BET method.The study evaluated the antibacterial activity of GKT against the standard strains of Gram-positive Staphylococcus aureus ATCC 25923 (SA) and Gram-negative Escherichia coli ATCC 25922 (EC). The photoinactivation of bacteria were examined in the dark and in the presence of UV-Vis light - LED system for 2h and the inactivation of bacteria by each test solution was cited. According to the analytical and morphological analyses, GKT was successfully stabilized by the crystalline structure and the presence of TiO2 was elucidated. In testes, GKT showed an inhibitory antibacterial effect of about 20% for S. aureus and 29% for E. coli without the presence of light, and 40% against S. aureus and 70% against E. coli when irradiated by UV-Vis. Bacteria irradiated by light did not follow bacterial inactivation, demonstrating that the lamp used did not influence the process of destruction of the bacterial cell membrane. Furthermore, the composite exhibited the anatase phase of the matrix to thus develop reactive oxygen species (ROS) responsible for bacterial inactivation, transmission of membranes, proteins, lipids and genetic material. Therefore, composite GKT is a promising material for antibacterial applications.

Clay-based nanocomposites are extensively investigated for their properties and diverse applications [1]. When clay minerals are functionalized with metallic oxides, they improve properties such as surface area and chemical and physical stability [2,3]. The present study evaluated the phytostabilization capacity of the ciprofloxacin when adsorbed on saponite pillared with Zr. The results of the nitrogen adsorption/desorption analyses showed a considerable increase in the surface area of the saponite after the incorporation of zirconia. Infrared spectra showed that the drug was effectively adsorbed on the material. The evaluation of the antibacterial activity of the hybrid - before and after the irradiation of the sample for 200 h (lamp 160 W, Hg) - shows the inhibitory effect on the colonies of S. aureus and E. coli. The nanostructured hybrids based on modified saponite are promising materials for biological applications or other approaches.

Water contamination with tetracyclines (TCs), which negatively affects the aquatic biota and the human health, has caused public concern and attracted scientific interest[1]. CeO2 has been one of the most reported lanthanide oxides in catalysis, it is usually studied as a adsorbent and photocatalyst for removing dyes and heavy metals[2]. A pyrolysis at low temperatures was used to transform a metal-organic framework of cerium and benzene-1,3,5-dicarboxylate to mesoporous nanostructured CeO2[3]. The confirm MOF formation and phase purity, PXRD, FTIR and TGA were carried out. TC solutions were submitted to a Fish Embryo Toxicity (FET) to evaluate the toxicity. The characterization confirmed the formation the material. The resulting particles have high capacity for adsorbing TCs from aqueous solution: 90 mg g-1 for 60 mg L-1 TCs. As a result, 98,75% of the initial TC concentration can be removed under simulated sunlight irradiation. According to kinetic analysis, the adsorption of TC onto the particles follows the Freundlich model and is a pseudo-second-order process. Thermodynamic analysis reveals that TC adsorption is exothermic and spontaneous. The embryotoxicity assessment on zebrafish embryos revealed that treatment with CeO2 particles significantly decreased the toxicity of TC solutions. The current contribution highlights attention to the significance of CeO2 in perspective of its interaction with their biological systems, revealing a competitive material that can be applied to real-world situations. We also note that the high surface area CeO2 that is reported here may also have properties suitable for application in other heterogeneous catalysis applications.

Scientific interest in the modulation of p-n-type semiconductor heterojunctions has grown, as these materials have shown promising results for photocatalytic applications [1]. Here it is reported that p-n heterojunctions can be applied in the photodegradation of methylene blue (MB). Thus, SnO2, CuO, SnO2/CuO materials with different Cu contents (5, 15 and 25%) were synthed by the precipitation and co-precipitation method. XRD results indicate formation of the rutile phase for SnO2, monoclinic for CuO and for the heterojunctions it was noticed that the addition of Cu caused the loss of crystallinity of the materials [1]. The bandgap energies obtained for the materials were 2.5; 1.4; 2.3; 2.0; 1.5 eV for SnO2, CuO and 5%, 15% and 25% heterojunctions, respectively. Raman spectroscopy showed Ag and Bg vibration modes for CuO and A1g and B1u for SnO2. For heterojunctions, the spectra showed that increasing copper content shifts the intense A1g peak of SnO2 to red, which may be associated with changes in the parameters of the SnO2 network [1]. Furthermore, the appearance of the Ag vibration mode in the SnO2/25% CuO heterojunction can be attributed to the formation of pure CuO species on the surface of the material, which was later confirmed by microscopy images. The reaction results using simulated sunlight revealed that the crystallinity was a determining factor in the activity of the materials, since the SnO2 obtained 55% of MB photodegradation, followed by the heterojunction SnO2/CuO 5% with 53%, the heterojunctions SnO2/CuO 15% and 25% got a reaction result of 37%. Finally, investigating the properties of p-n heterojunctions based on SnO2 and CuO can positively influence the design of efficient materials for photocatalysis induced by simulated sunlight, with potential application in the decontamination of several classes of dyes.

e-mail: jozielmateriais@gmail.com

ZnO-based photocatalysts are materials that have excellent performance in removing contaminants due to their good electronic properties and excellent thermal/chemical stability. ZnO presents easy aggregation of particles, non-toxic nature, high surface area, high bandgap and difficult recovery in the reaction medium and, therefore, strategies to immobilize them in different substrates are used to modify the optical performance of photocatalysts from chemical modifications (doping, incorporation, variations in thermodynamic parameters) [1-3]. In the case of doping with metal ions, the bandgap value can be reduced, and its absorption extended to wavelengths in the visible region. In addition, optimized tests are needed on experimental design, synthesis conditions, particle size and structure, and operational parameters (the effect of catalyst amount, the effect of pH, the nature and intensity of light, the effect of oxidizing agent) to improve removal efficiency at low cost [3]. Therefore, this review focuses on recent advances in ZnO-based photocatalysts, such as methods, chemical modifications, choice of organic contaminants in the photocalytic reaction, toxic effects and degradation pathways after effluent release in aquatic matrices, therefore, ZnO is a promising candidate for future research and scientific development.

An alternative to lower SOFC temperature is the use of perovskite-type ceramic materials, such as yttrium-doped barium zirconate ($BaZr_xY_{1-x}O_{3-\delta}$, BZY), with protonic conductivity [1]; BZY shows excellent chemical stability and grain conductivity, and finds application not only in SOFC technologies, but also in solid oxide electrolysis cells (SOEC), to produce hydrogen through water splitting [2]. In contrast, it presents poor sinterability, with low densification even at higher sintering temperature the average grain size remains small, and a high grain boundaries area increases resistivity. This behavior is associated to refractoriness but is observed a lack of systematic works to effectively study the cause [3]. In this work, $BaZr_xY_{1-x}O_{3-\delta}$ samples (x=0.2), were produced through solid-state reaction; we were able to obtain samples with 98% of theoretical density after sintering at 1600°C without sintering aid. We proposed a model, based on SEM microstructure and EDS analysis, to the effective reason of poor sinterability, being the formation of a secondary phase at grain boundaries, characterized as an yttrium oxide-rich phase, segregated at boundaries and decreasing the electrical conductivity; electrolytes have a high grain conductivity, but the total conductivity is limited by grain boundaries.

e-mail: ariilopes2@gmail.com

Photocatalysis, which utilizes abundant, clean, and renewable solar energy, is a promising technology for environmental remediation [1]. Titanium dioxide (TiO2) is one of the most promising materials for photocatalysis, but its efficiency is low in the visible spectrum region due to its high bandgap [2]. To improve its efficiency, researchers have searched fornew materials that exhibit good photocatalytic activity in both the ultraviolet (UV) and visible regions. In this study, TiO2 nanoparticles doped with different concentrations ofcobalt ($Ti_{1-x}Co_xO_2$) were synthesized using the modified Pechini method. The samples werecalcined for two hours at a temperature of 500°C, and preliminary characterizations indicate that both the pure and doped samples crystallize in the anatase phase. Furthermore, the morphology of the nanoparticles changes from a more regular pattern inthe pure samples to a more granular one in the Co-doped samples. Photodegradation testsof methylene blue dye using UV light indicate a higher rate of degradation in samples withlower Co concentration. The results suggest that Co-doped TiO2 nanoparticles could bepromising candidates for photocatalytic applications.ACKNOWLEDGEMENTS:FAPESP (2022/02994-20), CNPq (155499/2022-0)REFERENCES:[1] C. TiO2 is a host candidate for europium ions (Eu3+) to perform metal-semiconductor hybrid due to their applications in optical devices, photocatalysis, and sensors. Here we report the synthesis and characterization of titanate nanotubes (TiNTs) anchored to Eu3+ complex to obtain (TiNTs/Eu(tta)3Phen) nanohybrid, where tta = thenoyltrifluoracetone and phen = phenanthroline, to investigate hybrid structure and photoluminescence properties. TiNTs were synthesized through hydrothermal synthesis and TiNTs/Eu(tta)3Phen hybrid was obtained by dispersing TiNTs in ethanol-SDS solution, followed by adding Eu(NO3)3 and ligands. XRD pattern reveals the anatase phase; from the FT-IR spectrum, it is found that the intensity of the band shifted towards below 1600 cm-1, indicating the formation of nanohybrid. TEM microscopy shows TiNTs are bigger and less fragmented than TiNTs/Eu(tta)3Phen hybrid. The EDS spectrum demonstrates the number of well-defined peaks relative to Ti, O, S, N, and Eu respectively, which support the presence of Ti, O, ligands, and Eu in the nanohybrid. UV-Vis spectrum suggests that the host act as an effective antenna. The photoluminescence spectrum displays a strong red emission corresponding to the 5D0-7F2 transition of Eu3+, in corroboration with fluorescence confocal microscopy images.

e-mail: claudia.vaz@ufrpe.br

In this study, a magnetic graphite nanocomposite (NGM) based on magnetic nanoparticles (NPs) and graphite nanosheets (GR) was developed as an adsorbent, in order to promote the adsorption of the textile dye reactive black 5 (RB5) from the dispersing medium. NGM was synthed through the hydrothermal synthesis method [1], and the Zero Charge Point (pHzcp) study was performed. For the characterization of NGM and its precursors, X-ray diffraction (XRD), Scanning Electron Microscopy (SEM) and infrared (IR) spectroscopy techniques were used. An analysis of the stability of RB5 as a function of the pH of the medium was also carried out. The statistical result of the NGM showed a discoloration efficiency (%D) above 90% in the removal of RB5, high adsorption speed, since it reached the adsorption equilibrium in 480 minutes of contact with the adsorbate and presented adjustments greater than 90% for the pseudo first order and second order kinetics, in relation to the adsorption equilibrium was reached around ~45 $mg.g^{-1}$[2]. The study shows that the NGM can be separated from the medium only through the application of an external magnetic field, presenting efficient adsorptive properties, thus showing that it is the main responsible for the removal of the dye.

Synergy between adsorption and photocatalysis: Application of the CuBTC@CuS composite in the decolorization of methylene blue

Metalorganic frameworks (MOFs) are porous and crystalline solid materials, resulting from the combination of metal ions with organic ligands, forming porous and highly permeable structures. Furthermore, the ability to control the chemical composition and structure of MOFs allows the creation of a wide variety of materials with unique properties and specific applications.[1] The effectiveness of the adsorption capacity of dyes by an adsorbent is influenced by the surface characteristics of the structure and the structural behavior. CuBTC MOF is highly valued due to its large internal surface area and high adsorption capacity, making it economical and safe to remove dyes from aqueous solutions such as methylene blue.[2] This makes the use of MOFs to remove dyes from aqueous solutions an attractive and efficient option. To maximize discoloration, photocatalysis is a technique that can be used to decolorize organic dyes. In this context, copper sulfide (CuS) has been studied as a potential photocatalyst due to its optical and electrical properties.[3] In this work, a new technique of partial modification of the structure of the MOF CuBTC is proposed, resulting in a new compound called CuBTC@CuS. The amount of CuS present in the MOF structure can be controlled by the concentration of HS^- used during synthesis. In the adsorptive process, the composite of CuBTC@CuS was superior to CuBTC, with adsorption of 64% vs. 46%. The composite showed even greater discoloration when irradiated, demonstrating an MB removal efficiency of 87%. Thus, synergistically, the CuBTC@CuS composite showed efficient adsorptive activity and photocatalytic efficiency, which enabled an excellent performance, making the system a promising decolorizer for effluents containing the MB dye.[1] Liu, X. T. et al., Coordin Chem Rev, 476, 214921 (2023).[2] Huang, D. et al., Chemosphere, 263, 127672 (2021).[3] Xiong, Y. et al., Polymers, 11, 1393 (2019).

Synthesis and characterization of Fe(III) and Ga(III) modulated MIL-88B metal-organic frameworks for enhanced stability in aqueous and oxidative environments

Gustavo Felix Bitencourt[1], Wandson Lukas do Nascimento Amorim[2], Herich Henrique Lafayete Bastos de Lima[2], Luana dos Santos Andrade[2], Thiago de Melo Lima[3], Wagner Alves Carvalho[2], Dalmo Mandelli[2]

e-mail: gustavofelixbitencourt@id.uff.br

Metal-organic frameworks (MOF) have become increasingly popular due to their unique chemical and structural properties that make them highly desirable for a variety of applications. MIL-88 is a specific family of MOF that consists of Fe(III) ions connected by dicarboxylate ligands, resulting in various pore sizes, shapes, and properties that make them ideal for different uses [1]. However, one major challenge with MIL-88 MOF is their tendency to undergo structural changes or collapse when exposed to water, acidic or oxidative conditions [2]. Hence, this work focused on the synthesis of different Fe1-xGax-MIL-88B and on the evaluation of structural parameters in harmful environments. The MIL-88B were synthesized similarly to methods in the literature [3]. The synthesis were made by modulating the precursor metal salts, FeCl3.6H2O (1-x mmol) and Ga(NO3)3.XH2O (x mmol), and used terephthalic acid as ligand. The reagents were mixed in DMF and NaOH was used as a modulator. The system was heated at 100 °C for 12 h. After cooling, the MOF was washed with DMF and EtOH, collected by centrifugation, and dried overnight at 110 °C. To evaluate the material's stability, tests of soaking MOF in water for 7 d and in H2O2 (0.65 M) at ambient temperature were made. Accordingly to FAAS and XRD, only Fe and Ga-MIL-88B showed iron and gallium leaching in the liquid phase, respectively, which correlates with the diffractograms before and after the tests. Thus, the synergistic effect between iron and gallium proved to be an effective strategy for stabilizing metal ions within the crystalline structure. In future studies, these materials will be evaluated in catalytic reactions and if the modulation of Fe(III) and Ga(III) also enhances others properties. Synthesis and Characterization of g-C_3N_4/C-dot forOrganic Compound Degradation under Sunlight

Marcus Paulo Prado Rodrigues[1], Lucas Vinícius Alves Dornelas[1], Ingrid Távora Weber[1]

[1]Universidade de Brasília (*Instituto de Química*)

e-mail: marcuspprodrigues@gmail.com

The availability and quality of water is one of the great challenges of the 21st century. Searching for water reuse alternative is a topic of first interest. In this work, the low cost and metal free g-C_3N_4/C-dot heterojunction was synthesized aiming its use as visible driven photocatalyst. The precursors, C-dot and g-C_3N_4, were prepared by hydrothermal and thermal heating respectively [1][2]. The g-C_3N_4/C-dot samples were also synthesized by hydrothermal methodologies [3]. The FTIR spectra showed that g-C_3N_4/C-dot showed peaks characteristics of heptazine rings, and a band gap of 2,78 eV were obtained. The fluorescence spectra showed a shift towards the visible region. The efficiency of g-C_3N_4/C-dot was evaluated using a solution of methylene blue at different concentrations. After 180 minutes under sunlight exposure of the solution with heterojunction presence, a discoloration of the solution was observed, indicating a favorable sign for its use in photodegradation.

The present of this work was to investigate the $SnO_2$and NiO photocatalysts, in addition to the SnO_2/NiO-5 % heterojunction, which were synthed by the precipitation and co-precipitation method. The surface, electronic and structural properties were determined by X-Ray Diffraction (XRD), Diffuse Reflectance Spectroscopy (DRS/UV-vis), Infrared Absorption Spectroscopy (FTIR) and N_2physisorption analysis using the method B.E.T. The photocatalytic activity of the systems was evaluated through the photodegradation of methylene blue, a potential organic environmental pollutant. A bandgap value of 2,38 eV for SnO_2, 3,37 eV for NiO and 2,0 eV for SnO_2/NiO-5% was observed, noting that the bandgap for the heterojunction exhibited a decrease compared to the oxides pure, which may be promising for activating this material with wavelengths in the visible range of the electromagnetic spectrum. In addition, the heterojunction presented a surface area value of 62,2 m^2/g^{-1}, higher than the individual. After 120 minutes of reaction in the presence of UV irradiation, the photocatalytic efficiency values of the materials were 54, 32 and 15 % for SnO_2, SnO_2/NiO-5 % and NiO, respectively. The result showed that for $SnO_2$and SnO_2/NiO-5 % heterojunction, which are materials with similar properties, there was a greater efficiency compared to pure NiO. Also, due to the decrease of the main characteristic band of methylene blue, located at 664 nm, the cleavage path of the chromophore structure was identified as the predominant photodegradation route present in the absorbance spectra of all photocatalysts. In general, it is worth mentioning that the literature presents few reports on the synthesis and use of the aforementioned systems in the photodegradation of contaminants.

e-mail: Renatogouveia2@outlook.com

In the search for sustainable ways to remedy the problems caused by the disposal of contaminated effluents, it is necessary to produce and adapt new materials. The heterogeneous process of photocatalysis is an allied technology because it's an economicaland ecological solution for the degradation of organic pollutants in water [1].

Calcium titanate (CTO) is known to have excellent photocatalytic performance in the degradation of organic and inorganic pollutants [2]. Zinc sulfide (ZnS) is a semiconductor with a fast generation of electron/hole pairs that lead to a good photocatalytic activity [3].

The CTO-ZnS heterostructure was obtained through the SAM method and SEM images revealed that the CTO consists of mesocrystals assembled from agglomerated microcubes. After the application of a ZnS coating, it was possible to identify the formation of a cloud of particles around parts of the CTO mesocrystals, thus forming the heterostructure.

Photodegration tests on Rhodamine B dye in the presence of CTO, ZnS and CTO-ZnS revealed that the heterostructure led to more extensive photocatalytic degradation (50.5%) in 30 minutes than CTO (10%). Furthermore, the degradation efficiency over CTO-ZnS increased to 95.7% after 180 min, indicating that the ZnS coating served to increase the degree of discoloration over time. These satisfactory results demonstrate that CTO-ZnS is apromising photocatalyst capable of accelerating the degradation of organic dyes, thus contributing to the decontamination of water resources.

In this work, by the Pechini method (Pec), $TiO_2$was obtained, no doping (TiO_2Pec) and silver doping (Ag-TiO_2Pec). Characterization was performed by Raman spectroscopy, x-ray diffraction (XRD), and uv-vis diffuse reflectance spectroscopy (DRS). Photocatalytic performance was analyzed by methylene blue (MB) photodegradation and UV-Vis spectroscopy. By Raman spectroscopy characteristic peaks were observed for TiO_2, close to 142, 200, and 395 cm^{-1}(νTi–O), and 637 cm^{-1}(νTi–O–Ti). The synthesized samples indicated increased intensity and narrowing of the peaks, typical of high crystallinity. Inverse behavior in doped samples indicated the influence of silver on the disorder of thecrystal lattice. In the regions, 142 cm^{-1}- 150 $cm^{-1}$and 195 cm^{-1}- 201 cm^{-1}, shifts of 8 cm and 6 cm were estimated, respectively, indicating the presence of silver. Wider bands can also indicate oxygen vacancies [1]. Proportions (anatase:rutile)% were estimated by XRD: TiO_2 Evonik®(72:28); TiO_2 Pec (89:11); Ag-TiO_2 Pec (37:63). The crystallite size (nm): TiO_2Evonik® (22.66); TiO_2Pec (13.71); Ag-TiO_2Pec (17.03) and lattice parameters (a=b≠c) (anatase; rutile) Å: TiO_2Evonik®(3.78≠9.53; 4.58≠2.95); TiO_2Pec (3.78≠9.53; 4.59≠2.96); Ag-TiO_2Pec (3.78≠9.53; 4.6≠2.95). Doped samples showed an increase in peak width and intensity ($\theta \approx 25$ °), and inversion of crystalline phases, predominantlyamorphous system [2]. By DRS, $\lambda_{max}$of absorption (nm) and band gap (E_g) eV: TiO_2Evonik®(358; 3.46); TiO_2Pec (393; 3.14). Photodegradation tests indicated discoloration of MB%: TiO_2Evonik® (100); TiO_2Pec (56.02); Ag-TiO_2Pec (35.84 %). In this work, by the sol-gel method (SG), TiO$_2$was obtained, without doping (TiO$_2$SG) and doping with carbon (C-TiO$_2$SG). Characterization was performed by Raman spectroscopy, x-ray diffraction (XRD), and uv-vis diffuse reflectance spectroscopy (DRS). Photocatalytic performance was analyzed by methylene blue (MB) photodegradation and uv-vis spectroscopy. By Raman spectroscopy characteristic peaks were observed for TiO$_2$, around 142, 200, and 395 cm^{-1}(νTi–O), and 637 cm^{-1}(νTi–O–Ti). The synthesized samples indicated increased intensity and narrowing of the peaks, typical of high crystallinity. Displacements in the range of 3 to 10 cm^{-1}, and a band around 800 cm^{-1}(C-TiO$_2$SG), indicated the presence of graphitic carbon (C) or carbon replacing oxygen atoms in TiO$_2$surface sites [1]. Proportions (anatase:rutile)% were estimated by XRD: TiO$_2$Evonik® (72:28); TiO$_2$SG (100:0); C-TiO$_2$SG (100:0). The crystallite size (nm): TiO$_2$Evonik®(22.66); TiO$_2$SG (10.03); C-TiO$_2$SG (7.95) and lattice parameters ($a=b\neq c$) (anatase;rutile)Å: TiO$_2$Evonik®(3.79≠9.54; 4.58≠2.95); TiO$_2$SG (3.77≠9.50); C-TiO$_2$SG (3.73≠9.37). Doped samples indicated broadening and reduction of peak intensity and size of smaller crystallites, indicating that carbon atoms may have influenced crystal growth and an amorphous system [2]. By DRS, $\lambda_{max}$of absorption (nm) and band gap (E_g) eV were estimated: TiO$_2$Evonik®(358; 3.46); TiO$_2$SG (371; 3.34); C-TiO$_2$SG (380; 3.26). Photodegradation tests indicated discoloration of MB%: TiO$_2$Evonik®(100); TiO$_2$SG (75.73); C-TiO$_2$SG (73.53). Acknowledgments Capes, CNPQ, FINEP, UFOB, C-Nano UNB, and Evonik®Brazil. Titanium dioxide (TiO_2) is a widely used photocatalyst, but it has some limitations that restrict its use, such as a high bandgap value (3.2 eV), which makes it inactive in visible light. $TiO_2$is often modified by the addition of carbon nanomaterials to form a hybrid material to improve its efficiency with visible light and eliminate the recombination of photogenerated electron holes. Graphene-based materials can be attached to TiO_2, resulting in synergic properties and increasing the functionality of the hybrid [1]. This hybrid material could be the future of photocatalysis, particularly in pollution remediation and, energy generation using sunlight [2]. The main aim of this study is to produce a hybrid material of $TiO_2$and graphene derived from biomass capable of degrading pollutants and generating hydrogen gas (H_2) through water splitting under visible light.

Synthesis of metal doped TiO_2 nanotubes through one-step anodization for photoelectrochemical water splitting

Eduarda de Castro Flach[1], Vinícius Hülsendeger[1], Tiago Falcade[1], Daniel Eduardo Weibel[1]

[1]Universidade Federal do Rio Grande do Sul

e-mail: eduardaflach1@hotmail.com

The utilization of clean solar energy is essential to provide energy supply for the future. Photoelectrochemical (PEC) water splitting (WS) is one of the most promising technologies for solar energy conversion into renewable fuels [1]. In that sense, TiO_2 has emerged as a strong candidate owing to its excellent stability, low cost, and nontoxicity. Besides, TiO_2 nanotubes (TiO_2NTs) obtained through anodization present an organized and larger surface area when compared to other nanophotocatalysts. Additionally, the thin walls of theNTs lead to a minor chance of charge carrier recombination increasing the WS reaction rate[2]. With anodization, the doping of TiO_2NTs can be accomplished during its synthesis to optimize electronic properties of TiO_2NTs. In this work, highly organized TiO_2NTs wereobtained through an anodization process for WS applications. Polished Ti foils were placedas anodes and Cu as cathodes in a beaker with electrolytes. A potential difference of 20-60 Vwas applied per 2h. The electrolyte contained ethylene glycol, H_2O, NH_4F, and metal salts.Thermal treatment was done at 500°C per 3h to increase crystallinity. Optical and morphological characterizations were done using UV-Visible spectroscopy and scanning electron microscopy (SEM). Photocurrent measurements and the material efficiency datawere obtained with PEC essays in KOH 1 mol L^{-1} using a high-pressure Hg/Xe lamp with 140W maximum power. TiO_2NTs obtained are anatase phase with a bandgap of 3.2 eV. SEM images show NTs of diameters of 40-120 nm. Photocurrent measurements show a 10-time photocurrent density increase after the anodization, reaching 1.6 mA/cm^2 at 1 V. Doped TiO_2NTs obtained through one-step anodization process are underway.

Water pollution due to toxic organic compounds is a serious problem nowadays since the legal regulations concerning disposal of chemicals into the natural environment are more and more restrictive. The main causes of surface water and groundwater contamination are industrial discharges. Polyoxometalates (POMs) are a class of inorganic anionic metallic oxygen cluster compounds with abundant charge and excellent physical and chemical properties, such as photocatalytic activities, strong electron acceptability, adjustable energy band structure, and reversible multi-electron redox properties. Additionally, they are also inexpensive and environmentally friendly. It has been reported that POMs@TiO2 compounds improved activity for the photocatalytic degradation of organic pollutants such as dyes. In this study, photocatalytic oxidation of methyl orange dye under irradiation a Halogen lamp 900 W have been tested over Cobalt ion-based polyoxometalate@ZnO photocatalysts, with different molecular weight. The degradation of methyl orange is up to 97% with Co7@ZnO in 30 min, up to 92% with Co5.5@ZnO and Co4@ZnO about 83% within 120 min, at conditions 6 mg/L concentration of compound and 2 mg/L concentration of methyl orange. Fast degradation was obtained with increasing of the molecular weight of POM photocatalyst. The degradation of MO showed that the combination of ZnO and Co-POM compounds can degrade methyl orange more effectively in aqueous solution.

Synthesis of silver nanostructures for catalytic applications

Water contamination poses ecological threats and reduces the availability of freshwater. Organic pollutants can resist degradation and cause bioaccumulation, becoming a global concern that needs to be addressed. The treatment of organic pollutants is not always adequate or efficient, so proper and effective remediation procedures need to be developed and implemented. Advancements in nanotechnology have shown that nanoparticles (NPs) present the potential for environmental remediation. NPs possess a high surface area/volume ratio, which can improve the sensitivity and performance of monitoring tools. Among these types of nanomaterials, silver nanoparticles (AgNPs) stand out.[1,2] Thus, in this work, we prepared AgNPs with different shapes for the catalytic degradation of the organic pollutant 4-nitrophenol, in water. The AgNPs were synthesized in an aqueous medium by chemical reduction methodology, using polyvinyl alcohol (PVA) and polyvinylpyrrolidone (PVP) as stabilizers, sodium borohydride as the reducing agent, and hydrogen peroxide for morphological control. The results obtained showed that AgNPs were successfully prepared using polyvinyl alcohol (PVA) and polyvinylpyrrolidone (PVP) with controlled shape, achieving nanospheres or nanoprisms. The prepared AgNPs successfully promoted the reduction of 4-nitrophenol to 4-aminophenol. Thus, AgNPs have the potential to be used as a catalyst for pollutants removal in water.

weicianne.d@acad.ifma.edu.br, email: marcelo@ifma.edu.br

Summary:

The growing human urbanization and industrialization has caused several problems to the environment, mainly related to water resources. In view of this problem, research has been carried out in order to seek solutions to minimize this contamination through photocatalysis, using semiconductors[1]. Among these semiconductors, niobates have been used for this purpose. Tin niobate (SnNb2O6), due to its semiconductor characteristics, crystalline structure and reduction potential, is an excellent material with photocatalytic properties However, due to morphological characteristics such as specific surface area, obtaining it is not so simple. In this sense, the technique of synthesis by combustion in solution will be used because it is a versatile and simple method, in addition it allows obtaining materials with high reaction yield, as well as obtaining powders with high surface area. Chemical processes and the X-Ray Diffraction (XRD) characterization technique that occurred in crystalline phases were carried out. Measurements of photocatalytic properties will be produced in a photocatalysis chamber, using lamps with visible radiation emission directly on the elements to be degraded (Rhodamine B and Methyl Orange in aqueous solution) together with the semiconductor powder[2].

Synthesis of WO_3/Nb_2O_5 heterostructure applied inorganic dyes removal from aqueous solution

Thaís Aparecida Rodrigues[1], Douglas Mendes da Silva Del Duque[2], Vagner Romito de Mendonça[2,1]

[1]Universidade Federal de São Carlos, [2]Instituto Federal de Educação, Ciência e Tecnologiade São Paulo

e-mail: thaisaprodrigues3@gmail.com

Water pollution, caused by dyes, is a global issue. Advanced Oxidative Processes have emerged as a viable solution to address this issue, with Heterogeneous Photocatalysis beinga popular process due to the formation of radicals with high oxidation power that can degrade organic compounds [1]. In this study, $Nb_2O_5$and WO_3were coupled to improve the properties for the photocatalytic process. The synthesis of isolated materials was based on previous reports. $Nb_2O_5$was synthesized based on the procedure reported by Leite et al. [2], and $WO_3$was prepared using the procedure described by Castro et al. [3]. For the synthesis of the WO_3/Nb_2O_5heterojunction, acid tungstic was dissolved in hydrogen peroxide (H_2O_2). To this solution was added ammonium niobium oxalate dissolved in distilled water and then $H_2O_2$was added. The volume was completed with distilled water and the solution was treated at 200 ºC for 24 h. Isolated materials were prepared for comparation in the same conditions. The samples were characterized, and the results showed the presence of $WO_3$and Nb_2O_5, indicating the formation of heterojunction. To analyze its photocatalytic properties, the samples were applied in photodegradation of MB and RhB dyes under UV light. The results showed that the heterojunction was more effective than the pure materials. Therefore, WO_3/Nb_2O_5heterojunctions have the potential to be applied in photocatalytic processes for the degradation of organic compounds.

Zinc oxide nanoparticles (ZnO-NPs) are used as semiconductors in photocatalysis and decontamination of pharmaceutical, textile industry, and domestic effluents. Different NPs morphologies can change the required properties in each application. Synthesis of ZnO-NPs was carried out with a modification of the method proposed by Sharma et al. [1,2]. The volume of 0.1M of $ZnSO_4 . 7H_2O$ was added dropwise (16μL/s) to 0.4M of NaOH (1:4M). The product obtained was washed in a cellulose filter under negative pressure and heated at 60°C for 1h followed by a controlled air atmosphere at 150°C in an electric muffle furnace. Thermal treatment in chemical synthesis was an important factor to convert secondaryphases as $Zn(OH)_2$to ZnO. The diffraction peaks by X-ray diffraction (XRD) match to hexagonal wurtzite structure. The morphology of ZnO nanosheets and particles (21±3nm) was evaluated by images of FE-SEM. The bandgap value for ZnO-NPs was around 2.26 eV. In photocatalysis with UV vis, the absorption of photons leads to the excitation of the electron from the valence band to the conduction band, generating holes in the valence band that can oxidize or reduce effective organic compounds [3]. Thus, the use of ZnO nanosheets in photocatalysis can be efficient in wastewater treatment.

Tin dioxide (SnO_2) has been widly investigated and used in different applications, especially in heterogeneous photocatalysis [1]. This work aimed to evaluate the influence of structural characteristics of SnO_2on the degradation process of dyes and drugs. The oxide samples were obtained by the polymeric precursors method and calcined at 700°C for 2, 4 and 6h, and characterized by X-ray diffraction (XRD), Raman spectroscopy, infrared (IR), UV-Visible (UV-vis) spectroscopy, Scanning Electron Microscopy (SEM), BET analysis and Zeta potencial measurements. XRD structural results of SnO_2samples confirmed the formation of rutile-like tetragonal crystalline phase (*P42/mnm*), with na increase of the long-range structural order as indicated by FWHM values and crystallite , showed the influence of calcination time on the structural organization of the materials, indicating greater. The Raman spectra confirmed the presence active modes and acoustic modes in SnO_2. Regarding the photocatalytic properties of the materials, the sample at 700 °C/2h with maximum efficiency of 91% in the decolorization of the cationic crystal violet (CV) dye and 65% in the of the anionic orange gelb (OG) in agreement with the Zeta potencial analysis. In relation to tetracycline antibiotic, 52% of its degradation was attained by SnO_2calcined at 700 °C/2h after 6h of reaction. Additionally, the influence of catalyst mass and dye concentration was studied.

ABO3-type mixed oxides have been acting as catalysts in the photodegradation processes of textile dyes, which have been presented as one of the main villains in relation to their impacts on the environment due to their complex treatment when present in water bodies [1]. In this context, the present work aimed to prepared alkaline-earth metals stannates and zirconates for applications in the discoloration of malachite green (MG) and Remazol Yellow Gold (RNL) dyes. The oxides were synthed by the modified pechini method and characterized by X-Ray Diffraction (XRD), Infrared Spectroscopy (IR), Raman and UV-Visible spectroscopy. MSnO3-based perovskites (Ba2+, Ca2+ and Sr2+), BaZr0.5Sn0.5O3 and BaZrO3 were successfully obtained, confirmed by XRD patterns. Raman spectra of stannates and zirconates revealed a lower degree of symmetry according to the modifier cation with the largest ionic radius (Ba2+) and a greater degree of symmetry in BaZr0.5Sn0.5O3. From the UV-Vis spectra, band gap values ranging from 3.25 to 5.01 e.V. were observed. In relation to the photocatalytic tests the BaSnO3 samples showed an efficiency of 88.9% and 91.2% discoloration of the MG and RNL, respectively, in 6 h of reaction. BaZr0.5Sn0.5O3 presented 77.5% efficiency for the VM dye in only 2 h. These results showed that structural order-disorder modified by network modifier cation positively influenced the photocatalytic performance of the materials.

Petroleum is one of the main natural resources used as a source of energy today. In the petroleum industry, the refining stage is the most polluting stage, which can contaminate soil, air and water. The high demand for water by refineries actually becomes a problem due to the large discharge of difficult-to-treat liquids into the environment. A significant part of the discarded effluents are composed of water produced from petroleum, which has inorganic salts, oil, grease and organic contaminants. Such components have recalcitrant characteristics and generate water pollution, affecting human health and causing ecological imbalance [1,2]. Phenol, one of the main components of petroleum, is present in water produced from oil and has high toxicity, low biodegradability, in addition to carcinogenic and mutagenic behavior. In view of the problem of effluent disposal, it is necessary to develop solutions so that these effluents are treated in an ecologically correct, sustainable and economical way. Photocatalytic processes are widely used for wastewater treatment, being responsible for the degradation of organic and inorganic contaminants [3]. In this sense, this work aims to produce TiO2 nanofibers doped with niobium in different concentrations as photocatalysts using the electrospinning technique, in addition to evaluating and characterizing the structural, morphological and photocatalytic properties of the synthesized material. The photocatalytic properties will be evaluated from phenol degradation under UV light.

Hydroxyl radicals (·OH) are responsible for photocatalytic oxidation reactions. For this reason, the identification and quantification of this radical becomes an important parameter in the evaluation of the activity and efficiency of a photocatalyst [1]. In the present work, tungsten trioxide (WO3) was synthed by the modified Pechini method, to be used in the photohydroxylation of terephthalic acid (AT), in order to evaluate the formation of ·OH. The material was characterized by X-Ray Diffraction, Infrared Spectroscopy and Raman Spectroscopy and Scanning Electron Microscopy. WO3 is an n-type semiconductor, whose crystalline structure depends on temperature, so the results indicated a tetragonal crystalline structure (α-WO3), after calcination at 800°C for 4 h. The emission spectra were analyzed in a spectrofluorimeter as a function of the reaction time, where the photogeneration of hydroxyl radicals by the semiconductor resulted in the formation of 2-hydroxyterephthalic acid, a highly fluorescent compound. Therefore, the production of ·OH was proportional to the irradiation time of the catalyst suspension with the terephthalic acid solution. The results, when compared to the blank, show the applicability of the WO3 catalyst, in which the high intensities after its use resulted in a high production of hydroxyl radicals, playing an important role for a good photocatalytic efficiency.

The pharmaceutical industry is one of the significant waste generators, and pharmaceuticals are among the most commonly assessed emerging contaminants [1]. To minimize the problems caused by persistent organic pollutants, advanced oxidative processes and remarkably heterogeneous photocatalysis have emerged as promising alternatives for degrading and mineralizing these pollutants in wastewater [2]. Photocatalysis using Zinc Oxide containing Ce was proposed to evaluate the efficiency of pharmaceutical degradation.Photocatalytic tests were conducted using different concentrations of the catalyst in suspension with the IBF drug solution, and the toxicity of the solution to Artemia salina wasalso evaluated. The tests analyzed the effect of pH and catalyst concentration over a maximum period of 120 minutes of exposure to UV radiation during predetermined timeintervals. The different reduction efficiencies of IBU were 60%, 46%, and 40% for catalystconcentrations of 0.5 g L^{-1}, 1.0 g L^{-1}, and 1.5 g L^{-1}, respectively. The photocatalytic performance was sensitive to changes in pH, with the acidic condition proving the most efficient, demonstrating good photocatalytic activity with an equivalent rate of 47%. Thetoxicity tests showed low mortality from the irradiated solution.

Use of iron oxide magnetic nanoparticles in the adsorption of Rhodamine 6G and Rhodamine B dyes

Ana Claudia Vaz de Araújo[1], Bárbara Souza Damasceno[2], Valéria Cristina da Silva[1]

[1]Unidade Acadêmica do Cabo de Santo Agostinho - UFRPE, [2]Instituto Tecnológico de Aeronáutica

e-mail: claudia.vaz@ufrpe.br

Rhodamine 6G (Rh6G) and Rhodamine B (RhB) are dyes widely used in industries, such as textiles, inks for printers, and lasers, among others. To minimize the environmental impact from the improper disposal of residues contaminated with these dyes, several types of effluent decontamination processes have been studied. The adsorption method has stood out in the treatment of these effluents, due to its ease of operation, low cost, and high efficiency. In this work, iron oxide nanoparticles (NPs) were synthed by co-precipitation and tested as adsorbents for Rh6G and RhB. The phase of the NPs was determined by XRD to be the cubic Fe3O4, with mean crystallite s around 46.3 nm. Scanning electron microscopy showed spherical morphologies for the NPs, with diameters around 51.0 ± 5.0 nm. The maximum absorption wavelengths for Rh6G and RhB were 526 nm and 554 nm, respectively. Both rhodamines were stable when the pHs of the media were changed, with no absorption changes in their visible spectrum. Adsorption tests of the rhodamines by NPs were carried out. The highest adsorption capacity occurred at pH 4.0 and the adsorption equilibrium at the contact time was close to 30 min. The Pseudo-Second Order model best described the adsorption kinetics, with a 99% adjustment, in comparison with other models. The Temkin model fit very well the adsorption isotherms obtained at 301, 311 and 321 K. The maximum adsorption capacity occurred in both dyes at a temperature of 321 K: 279.51 mg g-1 for Rh6G and 276.64 mg g-1 for RhB. This study shows that the synthed NPs are efficient adsorbents for rhodamines in aqueous medium. Furthermore, the NPs can be easily removed from the medium through the application of an external magnetic field, making this a promising system for the treatment of effluents.

Use of reactive species to understand the behavior of TiO2/Ag photocatalysts

Taiane Silva dos Santos[1], Adervando Sebastião da Silva[2], Iêda Maria Garcia dos Santos[3]

[1]Universidade Federal da Paraíba (*Química Bacharelado*) , [2]Universidade Federal da Paraíba (*ccen*) , [3]Universidade Federal da Paraíba (*Departamento de Química*)

e-mail: taishig@hotmail.com

Despite the known contamination of aquatic environments by different pollutants, cheap efficient treatments for contaminated water are still not a reality. One of the forms of remediation is photocatalysis. In the present study, changes in photocatalytic processes after photodeposition of Ag on the surface of commercial TiO2 were evaluated. One way to evaluate the species active in photocatalysis is by the use of substances that react with the hole, removing them from the solution and reducing the photocatalytic activity, which was done with EDTA addition into the solution [1]. To avoid the reaction of electrons with O2 dissolved in water, the reaction was carried out in a stream of N2. Materials were characterized by X-ray diffraction (XRD), infrared absorption spectroscopy (IR), Raman spectroscopy and scanning electron microscopy (FEG) coupled to EDS. The presence of Ag on the sample was confirmed by the positions of the surface plasmon resonance bands in the UV-vis spectra, besides a color change of the samples. XRD patterns displayed a peak assigned to Ag at 44º. FEG/EDS analysis confirmed the deposition of Ag on the TiO2 surface, while zeta potential indicated a change in the surface charge after Ag deposition, particularly at low pH values. The fluorescence spectrophotometer allowed us to analyze the behavior of the TiO2/Ag composite in the formation of hydroxyl radicals, by the photohydroxylation of terephthalic acid, with EDTA addition or under N2 flow. EDTA addition decreased the amount ·OH radicals, reducing the photocatalytic activity, confirming the participation of holes in the photocatalytic process, for all samples. N2 flow also decreased the photocatalytic activity, which indicates that the process of excitation of electrons to the higher energy band and subsequent reaction with O2 was effective. e-mail: davi.correia@ufpe.br

Contamination of water resources by dyes is one of the most serious ecological threats. Dyes often reveal toxic, carcinogenic, and mutagenic properties [1]. Among water treatment methods, adsorption is one of the most efficient for separating dyes from wastewater [2]. One of the most efficient sorbents for dyes are Metal-Organic Frameworks (MOFs). They are porous coordination polymers, with large specific surface areas, variety of active sites, and affinity to ionic and non-ionic molecules [3]. In this work, the capacity of dye adsorption was evaluated in batch adsorption experiments at room temperature using several dyes (cationic and anionic) and a bimetallic MOF (FeCo-BDC). The FeCo-BDC was characterized by FTIR, PXRD, and SEM-EDS. The FeCo-BDC exhibited a pure crystalline phase and adsorbed over 80% of anionic dyes in only 20 min of phase contact. The excellent adsorption capacity can be attributed to the ionic interaction between the active sites of the MOF groups and the dyes.

The compounds formed by imidazole ligands form crystalline structures known as ZIFs (Zeolitic Imidazolate Framework), are materials that have well-defined structures of high stability, crystalline, porous and have a large surface area [1], the obtaining of materials supported on solid substrates, that have as characteristics of acting as potential photocatalysts, promotes what we call third-generation materials [2]. In this work, the material called (ZnIm-NTT), was developed by joining of the zinc-imidazolate framework [Zn2(C3H3N2)4]n (ZnIm) [3] formed in situ on TiO2 nanotubular structures (previously obtained by anodization) via hydrothermal synthesis. The diffractogram of the material produced by XRD shows the obtaining of a high crystalline material, with SEM and EDS analysis it is possible to see the structure deposited on the nanotubular surface and its chemical characterization. The compound was applied as a photocatalyst for the degradation of the persistent organic pollutant (POP), methylene blue dye in the concentration of 15 ppm, via simulated solar radiation, promoting a percentage of color removal of over 96 % after 450 minutes. These results show evidence that the third generation material obtained, here has a potential application in the treatment of persistent organic pollutants.

Zinc molybdate synthed by the Pechini method and evaluated as photocatalyst

Lays Amorim Colaço[1], Samuel da Silva Lima[2], Iêda Maria Garcia dos Santos[3] [1]Federal University of Paraíba (*Engenharia de Materiais*) , [2]Universidade Federal da Paraíba (*Química*) , [3]Universidade Federal da Paraíba (*Departamento de Química*)

e-mail: layscolaco@hotmail.com

In the last years, transition metal molybdates (AMoO4, A = Cu, Zn, Co, Ni and Ca) have been widely studied due to their structural, electronic and catalytic properties. This versability of catalytic properties are related to the different oxidation states that molybdenum may have. Among these compounds, zinc molybdate has been applied as photocatalyst, with interesting results. In the present research, zinc molybdate was synthed by the modified Pechini method; characterized by X-ray diffraction, infrared spectroscopy, Raman spectroscopy, nitrogen adsorption and scanning electronic microscopy; and applied as photocatalyst in the degradation of methylene blue (MB) and in the photohydroxilation of therephtalic acid (TA). A single-phase material was obtained with triclinic structure, ·-ZnMoO4. Photohydroxilation results indicated that a small amount of hydroxyl radical was formed, indicating that the indirect mechanism is not the main process of photodiscoloration. This result is similar to those obtained for MoO3 by our research group. In this case, photocatalysis may occur by the direct mechanism, with the electron transfer between the photocatalyst surface and MB.

e-mail: pedro.ponce.o@uni.pe

The aim of this work is ciprofloxacin (CIP) removal using a $ZnO/TiO_2/Ag_2Se$ compound by photoelectrocatalytic reactions. The material was prepared as follows: first, the ZnO seeds were electrodeposited onto FTO conducting glass, followed by hydrothermal treatment to turn them into nanorod a second process uses the sol-gel method (dip-coating) for TiO_2synthesis and a third, for synthesis and Ag_2Se electrochemical deposition. The XRD diffraction peaks can be indexed as hexagonal wurtzite structure ZnO, the presence of TiO_2in its anatase form and of the Ag_2Se orthorhombic phase. FTIR spectroscopy shows the ZnO, $TiO_2$and Ag_2Se bands at 582, 848 and 1666 cm^{-1}respectively. Raman spectroscopy showed the presence of the TiO_2anatase phase. The SEM-EDS images displayed ZnO nanorods presence coated by TiO_2particles, as well as Ag_2Se coating the $TiO_2$and ZnO surface, as dispersed nanoparticles. Synthetic water containing 5 mg dm^{-3}CIP solution in 0.75 mol L^{-1}NaCl at pH 7 was used to study photoelectrocatalytic behavior of $ZnO/TiO_2/Ag_2Se$ compound, attaining 71% CIP decay after 3 h at bias potential +0.80V vs Ag/AgCl under irradiation with blue LED lamp 440 nm.

H-New Developments in Battery Materials: Designing and Producing More Efficient Systems via Nanoscale Characterization

Controling the electronic properties of graphene nanoribbons towards energy applications.

Paola Ayala[1]

[1]Universität Wien (*Physics*)

e-mail: paola.ayala@univie.ac.at

Graphene nanoribbons are quasi 1-dimensional materials consisting of strips of graphene with a defined width and edge structure. This geometry also defines their electronic and optical properties, which implies applications in various fields of nanotechnology. This work focuses on ultra-narrow graphene armchair nanoribbons (AGNRs) encapsulated inside single-walled carbon nanotubes (SWCNTs). These AGNRs belong to the N=3p+2 family, and are expected to have small but non-vanishing band gaps. It has been reported elsewhere that the Raman response of the precursor molecule that remains outside the tubes can be discerned from that of the inner GNR. Inspired by this possibility we have explored the influence of the encapsulation on the band gap of the GNR, which has never been measured using optical characterization techniques to the best of our knowledge. To better understand the properties of this one-dimensional material we have performed Fourier Transform Spectroscopy (FTS) on a broad energy range from 0.1 to 2.5 eV. We have found both a reduction and a shift of the E11 excitation of the SWCNTs as a result of the interactions between the ribbon and the host. A GNR band gap for encapsulated ribbons could be estimated to lie around 0.19 eV, smaller than for free standing GNRs as expected from DFT calculations. Optimizing the properties of such hybrid materials offers tremendous opportunities for applications in energy related applications.

Dynamic stability design for advanced solid-statebatteries

Xin Li[1]

[1]Harvard University

e-mail: lixin@seas.harvard.edu

Solid state battery is a mechanically more coupled device than the commercial liquid electrolyte Li-ion batteries. Mechanical constriction effect strongly modulates the electrochemical stability at all interfaces in a solid-state battery. This effect introduces some unique dynamical evolution of interface reactions upon battery cycling, understanding of which is challenging but also giving us an opportunity to design the battery performance beyond commercial Li-ion batteries. The talk discusses the design of "dynamic stability"; at various interfaces for a stable long cycling of Li metal anode solid state batteries, where Li dendrite penetration can be suppressed through this dynamic process at high current densities. Advanced characterization will be combined with simulation to elucidate mechanistic details.

Imaging Characterization Challenges and Solutions for Advanced Battery Development

Zhao Liu[1]

[1]Thermo Fisher Scientific (*MSD*)

e-mail: zhao.liu@thermofisher.com

Lithium battery is an energy storage system with highly complex microstructures covering multiple length scales, namely from millimeters to nanometers. The performance of the battery is dependent on the battery microstructures. Therefore, accurately characterizing the battery microstructure at different length scales is critical for interpreting battery performance, which ultimately advances battery technology.

Imaging characterization via electron microscopy, including SEM, FIB-SEM, and TEM, has been recognized as an effective approach to studying battery microstructure. However, it is challenging to capture the materials at the full-length scale and also correlate each data set. In addition, some materials are beam-sensitive and air sensitive, making it challenging to observe the structure at its native state.

In this talk, I will discuss a couple of challenges in imaging characterization on battery materials and how to use a comprehensive approach to study the battery structure at multiple length scales in 2D and 3D. In addition, solutions such as cryogenic FIB and TEM, inert gas sample transfer, and dose management approach to observe the battery materials are their native state will also be discussed.

Understanding $LiNi_xCo_yMn_zO_2$ battery cathodes by advanced transmission electron microscopy

Paulo J. Ferreira[1, 2, 3]

[1] INL - International Iberian Nanotechnology Laboratory, Av. Mestre José Veiga s/n, 4715-330 Braga, Portugal

Abstract

$LiNi_xCo_yMn_zO_2$ (NCM), a common cathode battery material, exhibits a specific capacity and operating voltage comparable to $LiCoO_2$, while being less toxic. It is reported that NCM is composed of a mixture of $LiMO_2$/ Li_2MnO_3 layers (where M=Ni, Co or Mn). $LiMO_2$ is associated with a trigonal (R3m) phase, whereas Li_2MnO_3 is associated with a monoclinic (C2/m) phase, which is responsible for storing and providing Li+ during Li-extraction of $LiMO_2$. Nevertheless, these layered materials exhibit a large degree of cation disorder, which disrupts the Li+ pathways and creates a continuous MO_2 layer, lowering the Li mobility and reducing the cycling performance. Yet, so far, these phenomena have been mostly studied in single-crystalline particles. However, at the industrial scale, the NCM produced is typically in the form of micrometer polycrystalline particles, where the primary particles possess a very complex microstructure, in particular an agglomeration of nanoparticles, porosity, as well as chemical and phase heterogeneity. In this regard, this work aims to fundamentally understand the changes in chemical distribution as a function of Ni content in polycrystalline NCM cathode materials. In particular, the chemical composition and structure of the NCM polycrystalline particles with Ni contents from 0.70 up to 0.90 wt. % were investigated using FIB-SEM, aberration-corrected STEM, EDS mapping and precession electron diffraction. Slice-and-view SEM/FIB analysis revealed a geode-like morphology, independently of the composition. Yet, as the Ni content increases, the particle porosity decreases. STEM-EDS revealed variations in chemical composition across a single particle, in particular Ni content. Despite precession electron diffraction results suggesting the presence of only one crystal structure, atomic-resolution STEM images revealed that variations in the composition may be related to the presence of orientation variants within a single crystalline grain.

Emerging strategies and technologies for TEM imagingof beam and air sensitive materials

Lee Casalena[1]

[1]Thermo Fisher Scientific

e-mail: lee.casalena@thermofisher.com

Designing less expensive, more efficient, and more reliable energy storage devices requiresa deeper understanding of the structural and chemical properties of the constituent materials. This area of research has been particularly challenging using traditional electron microscopy characterization methods, as many of these materials are highly sensitive to air and moisture, as well as the electron beam at standard dose levels.

Preserving these materials in a fully inert atmosphere throughout the sample preparation, imaging, and analytical stages requires improved integration and hardware interfacing between complementary techniques. Once in the TEM, precise measurement and control of the electron dose is critical to reproducible experimentation. This is achieved through new software innovations and improved source and detection hardware.

Large solid-angle EDX detectors are needed to map out sample chemistry in 3D without damaging the structure. Dose-efficient imaging techniques such as integrated differential phase contrast (iDPC) coupled with new single-electron sensitive detectors have been key advancements to resolving structure of delicate materials. Furthermore, working at cryogenic temperatures is often a requirement alongside these strategies to ensure sample integrity and validity of experimental results.

Nanoscale structural analysis of iron oxide crystallites using electron diffraction-based Pair Distribution Function (e-PDF) technique

Naga Vishnu Vardhan Mogili[1], Jefferson Bettini[1], Edson Roberto Leite[1], Joao Batista Souza Junior[1]

[1]Brazilian Center for Research in Energy and Materials

e-mail: vishnu.mogili@lnnano.cnpem.br

Magnetic materials of spinel iron oxide compounds such as magnetite and maghemite have recently received immense interest due to their potential applications in various fields. Studying the atomic structure of these nanomaterials is essential to understand their unique properties. Traditionally, the structure of the material is determined from the Bragg peaks in the diffraction patterns. As the size of the nanomaterial is reduced, the fine powder crystallites lack structural coherence, and the diffraction patterns show broad Bragg peaks along with a pronounced diffuse component. This renders the application of classical powder diffraction techniques to be challenging for structural characterization. To overcome this, considering both Bragg and diffuse scattering, different total scattering methods were developed, and Pair Distribution Function (PDF) is one of them. Due to theability to deliver a large elastic momentum transfer range (q_{max}), neutron and synchrotron sources are generally considered to be favorable options for PDF studies. However, with theadvent of superior detector systems and better control of parallel or tilted electron beams inaberration-corrected TEMs, it is now a common practice to obtain $q_{max}$of 30 Å^{-1}and performhigh real space resolution e-PDF studies. Given this, the large scattering cross section associated with electrons is generally subjected to multiple scattering effects. Previousworks show that the electron scattering related to dynamical effects can be limited by reducing the specimen thickness, but with the change in electron energy, its impact is notvery clear. In the present work, the multiple scattering effects in 4 - 5nm sized iron oxidecrystallites were explored, and quantitative data treatment of e-PDF profiles acquired atdifferent beam energies is illustrated.

Poly(o methoxyaniline) modified by the BiphasicCeramic System $Na_2Ti_3O_7$/ $Na_2Ti_6O_{13}$

Juliana Pereira da Silva[1], Salomao Costa[2], Leandro Aparecido Pocrifka[3], Yurimiler Leyet Ruiz[4], Lianet Aguilera Domínguez[5,6]

e-mail: juliana_sp93@hotmail.com

POMA is a conductive polymer similar to polyaniline and presents electrical conductivities in the range of 10^{-1}-10^{-4} S cm^{-1}[1]. On the other hand, sodium titanates are semiconductor ceramics reported as good alternatives for application as solid electrolytes, with electrical conductivity values of 10^{-6} S cm^{-1}[2]. We probed the structural modifications and electronic behavior of composites obtained from the mixture of a biphasic titanate ceramic system ($Na_2Ti_3O_7$/$Na_2Ti_6O_{13}$) with a poly(o-methoxyaniline, POMA) matrix. The composites were obtained by the addition of $Na_2Ti_3O_7$/$Na_2Ti_6O_{13}$ to a POMA matrix in mass concentrations from 0 to 35 %. The sodium titanates were synthed by means of sonochemistry, while the polymer was obtained by conventional chemical polymerization. The structural analysis carried by XRD, FTIR and UV-Vis indicated mostly the presence of POMA, though the titanates could be identified in the composites with higher concentration. The XRD difractograms showed narrow reflections that could be correlated to the $Na_2Ti_6O_{13}$ phase and hydrogen titanates, whose presence indicates a process of partial substitution of H^+ for Na^+ ions. While the thermal degradation of the polymeric chains starts near 150 °C, the thermogravimetric and diferential thermogravimetric (TG/dTG) analysis revealed that the presence of sodium titanates enhances the thermal stability of the composites. Finally, the addition of the biphasic ceramic to the composite increases the electrical resistivity drastically, from 10^2 Ω cm in the pure POMA to 10^4 Ω cm in the 35 % composite.

Fuel cells are electrochemical devices that use redox reactions to convert ionic currents into electricity. It is a clean and sustainable energy because it generally uses hydrogen in the protonation with oxygen gas, obtaining water and non-toxic gases as products [1]. This energy can power an airplane, truck, car, electric bicycle and also a scooter. Currently, there are some studies to integrate biofuel cells to the implantable medical devices (IMD), such as stents, pacemakers, cardio-defibrillators and robotic prostheses, but these researches are in an early stage [2]. In the state-of-the-art highlight, an artificial blood solid-state-biofuel cell to power an IMD have been developed. Polycaprolactone (PCL) was subjected to electrospinning to form a nanofiber membrane. A part of it was modified with metallic sodium as anode electrode and hydrogen storage. Other part, it was modified with 5 W laser semicondutor to obtain laser induced graphene (LIG) as cathode electrode and oxygen diffusion. Furthermore, a proton exchange membrane (PEM) by incorporating hydrogen protons inside the PCL/poly-oligopeptide blende have been obtained. The edges of the solid-state-biofuel cell (1 cm^2) were sealed by a thermal junction with PCL (60 to 70 ºC) and characterized on artificial blood samples for potential and electric current measurement.

Theoretical Study of the solid-state electrolyte $Li_3PS_4$and the interfaces formed with Li_2S and Li-anode

Naiara Leticia Marana[1], Mauro Francesco Sgroi[1], Anna Maria Ferrari[1], Silvia Casassa[1], Lorenzo Maschio[1]

[1]Università degli Studi di Torino (*Chemistry*)

e-mail: naiaraleticia.marana@unito.it

In recent years, solid-state lithium batteries (ASSLBs) have been investigated for their various qualities, including safety as they are non-flammable materials. Among them, sulfur-based solid electrolytes, such as lithium thiophosphate, Li_3PS_4, have drawn attention due to their good ionic conductivity, (the β-structure has an ionic conductivity of about 3.0 $x10^{-2}$ Scm^{-1} at 573 K)[1]. However, one of the problems that arise when it comes to ASSLBs is thatof interfaces and their defects, in particular the Li dendrites, which can compromise the correct functioning of the battery and the Li-ion migration. In this sense, understanding how interfaces and their defects are formed, and how we can avoid them, is a fundamental point for the advancement in the development of commercial batteries. Therefore, this work aims at exploring, from a theoretical point of view, the formation, stability, and properties of the interfaces formed between the stable surface (110) of β-Li_3PS_4 solid electrolyte[2] with the Li-anode and Li_2S, a passivating material that should stabilize the Li_3PS_4/Li-anode interface. Furthermore, possible pathways for the migration of Li-ions across the interfaces were hypothed based on the electron density critical points obtained through topological analysis.

e-mail: juliana_sp93@hotmail.com

Membranes obtained by the addition of sodium titanates ($Na_2Ti_3O_7$/$Na_2Ti_6O_{13}$) in a polyvinyl alcohol (PVA) matrix of are reported for the first time. The synthesis of sodium titanates occurred through high-intensity ultrasonic irradiation and subsequent heat treatment. PVA is a polymer used in solid electrolyte membranes because of its non-toxicity, easy formation of thin films, good water solubility, high chemical resistance, high tensile strength and flexibility and good capacity for storing charges[1-2].On the other hand, sodium titanates are semiconductor ceramics reported for application as solid electrolytes, with electrical conductivity values of 10^{-6} S cm^{-1}[3].Then, the three types of composites were produced using the solvent casting method: a sample of PVA polymer, a second PVA composite with the addition of $Na_2Ti_3O_7$/$Na_2Ti_6O_{13}$without heat treatment (NTO-WTT), and a third sample with heat-treated $Na_2Ti_3O_7$/$Na_2Ti_6O_{13}$. The analysis by FTIR allowed the identification of functional groups of the PVA polymeric chain, and the presence of the two sodium titanates phases RAMAN were detected by RAMAN. AFM showed n increase in the mean surface roughness of the PVA (~ 1.9 nm) to the maximum value of ~ 40.1 nm for the NTO-WTT sample. Finally, the sample NTO-WTT showed the lowest value of electrical resistance (10^5 Ω) and relaxation time (3.16 x 10^{-5} s). Therefore, the presence of these ceramic particlesin the PVA matrix improved its semiconductive properties and potential to electronic applications.

Carbon nanotubes have excellent physical, chemical, mechanical, and thermal properties that make then attractive for many applications. However, the low interaction with most ofthe solvents and the tendency to agglomeration, make them difficult to use [1]. Thus, thisstudy aimed to functionalize the carbon nanotube with lignosulfonate and evaluate thecolloidal stability of the system. Dispersions with distinct nanotube amounts were prepared, using lignosulfonate as dispersing agent, with the aid of an ultrasound bath.

The effect of dispersion was evaluated using X-Ray Diffraction (XRD), Infrared Absorption Spectroscopy (FTIR), Scanning Electron Microscopy (SEM), Thermogravimetric Analysis (TGA), Raman spectroscopy and Zeta Potential. The functionalization was confirmed by means of FTIR, TG and SEM. The addition of lignosulfonate does not change the crystallinity patterns of the nanotube and did not promote the introduction of defects, which was confirmed in the XRD and Raman techniques, respectively, indicating a non-covalent functionalization. Carbon nanotubes dispersions prepared with lignosulfonate showed good colloidal stability during several months, and were applied in negative electrodes of lead-acid cells. Well-distributed carbon nanotubes were observed within the bulk electrode, enhancing the efficiency to accept charge, especially in partial state of charge, which was confirmed by electrical charge acceptance tests.

Hydrothermal synthesis of alumina nanoparticles for electrode coatings of Lithium-ion batteries

Camila Louyse Oliveira da Rocha[1], Antonio Eduardo Martinelli[1], Armando Monte Mendes[1]

[1]Universidade Federal do Rio Grande do Norte (*ENGENHARIA DE MATERIAIS*)

e-mail: camila.louyse26@gmail.com

Despite their low weight and long service life, lithium-ion batteries (LIBs) have some limitations such as degradation and risk of fire in case of overheating [1]. Some nanomaterials for coating electrodes have become a solution to improve the performance of LIBs. Among them, alumina (Al_2O_3) has stood out due to the reduction of electrode degradation during charge and discharge cycles, in addition to improving heat dissipation [1]. Al_2O_3 can be synthesized by several techniques, but the hydrothermal synthesis route has been highlighted due to the efficient control of the size and morphology of nanoparticles [2]. The objective of this work is to synthesize nanostructured Al_2O_3 by the hydrothermal method, at temperatures as low as 175°C for 1 h, using precursors such as aluminum nitrate and urea. X-ray diffraction (XRD) results indicated the characteristic peaks of γ- Al_2O_3. From the results of Fourier transform infrared spectroscopy (FTIR), the formation of O-H and Al-O bonds, which are characteristic of γ- Al_2O_3, could be verified. Scanning electron microscopy with field emission gun (FEG-SEM) showed nanoparticles with well-defined plaque morphology and low agglomeration.

Inert gas sample transfer workflow for lithium-based battery characterization

Zhao Liu[1]

[1]Thermo Fisher Scientific (*MSD*)

e-mail: zhao.liu@thermofisher.com

One of the key methods for achieving the understanding of the battery materials structure has been through techniques such as DualBeam (FIBSEM) lamella preparation and subsequent TEM analysis. However, due to the air and moisture sensitivity of certain battery components, maintaining sample integrity for characterization has been a challenging task. This poster will present an approach for analyzing lithium-based battery materials in their native state using an inert gas sample transfer workflow.

The development of efficient batteries has been a major challenge for industry and scientists, since they must meet certain criteria, such as: high efficiency - providing a large amount of energy at a good cost-benefit; be safe and have clean energy from renewable sources. Therefore, the study of ionic conductors has been important because they meet these requirements and have a high ionic conductivity, due to the movement of atoms or ions at temperatures much lower than its melting point. In recent years, special attention has been paid to sodium titanate ceramics (NTO) due to its high ionic conduction at room temperature. In this work, the influence of pH on synthesis, conventional and laser sintering, and electrical characterization of $Na_2Ti_3O_7$ ceramics was done. $Na_2Ti_3O_7$ powders were synthed by the polymeric precursor method, changing the pH of the solution from 0 (as prepared) to 11, and calcined at 500 °C for 5h. The ceramics were conventionally sintered in an electric oven at 1040 °C for 2 h and laser-sintered, using a CO_2 laser as heating source. In both cases the samples produced from pH 0 showed higher relative density and homogeneous microstructure. All samples produced showed majority the $Na_2Ti_3O_7$ phase. The electrical conductivity of the sintered ceramics was approximately 10^{-4}S. cm^{-1}.

Structural and electrical properties of polymer electrolytes synthed by solution casting

e-mail: carlosyago1996@gmail.com

In recent decades, with the advent of new electronic devices and the growing demand for energy, researchers have sought new sources of energy storage[1]. Since then, lithium-ion batteries (LIBs) have gained particular attention. Because of this, different electrolytes have been studied. Polymeric solid electrolytes have considerable advantages, such as high flexibility and low cost, being more suitable for mass production [2], receiving special attention. This work presents the synthesis and characterization of polymeric electrolytes in the form of lithium-doped films varying the proportion of polymers using the solvent casting method. This method is effective for forming a uniform film. Poly(vinyl alcohol)-PVA and poly(vinylidene fluoride)-PVDF were the polymers used and N-Methyl-2-pyrrolidone solvent was used as dispersion medium. The results of Complex Impedance Spectroscopy revealed that the electrolyte with 75%PVA 25%PVDF 1% Li presented low resistance in the order of 102, indicating in this proportion the formation of an electrolyte with good electrical properties. The X-Ray Diffraction technique revealed that there was the formation of the PVA and PVDF phase and the cohesion between them. The characteristic peaks of PVDF are centered at $2\theta = 18.3°$, $2\theta = 19.9°$, $2\theta = 26.06°$ and of PVA at $2\theta = 19.6°$ and 22.3°. Infraredspectroscopy is in accordance with the literature and presents profiles following a patternwhen PVA is added to the structure, appearing vibrational bands with changes in intensityin others. Finally, this work reveals that electrolytes with adequate proportion, have potential to be used in energy storage devices.

Many of the studies on polymeric electrolytes have been focused on enhancing their properties, such as increasing ionic conductivity at room temperature [1]. One way to achieve high ionic conductivity is by mixing polymers. These mixtures gave way to a new form of processing, becoming commercially and technologically more important than the manufacture of homopolymers and copolymers that until then were valued [1-2]. For this reason, this work presents the synthesis and characterization of polymeric electrolytes doped with lithium and graphene by the solvent casting method. Poly(vinylidene fluoride)-PVDF and poly(vinyl alcohol)-PVA were the polymers used in the proportion 75%PVA 25%PVDF with 9% Li. The amount of graphene doped was 0.5%, 1%, 1.5% and 2%. Results showed that the electrolyte with 1.5% graphene showed the best response in terms of electrical resistance, in the order of 101, possibly because graphene contributes to the dispersion between PVA and PVDF and conductivity in the order of 2.5 x 10^{-4} S/cm X-Ray Diffraction revealed the phase formation of the materials and confirmed the presence of graphene. Finally, this work reveals that the electrolyte 75%PVA 25%PVDF 9% Li - 1.5% graphene can be used as an electrolyte for Li-ion batteries.

The study of foldable batteries without safety risks is a crucial task for the realization of portable and wearable electrical devices. Given these concerns, the development of solid-state batteries is one of the most promising routes to achieving this quest. In this work, a study was carried out with polymeric electrolytes composed of poly (vinylidene fluoride) PVDF and poly (vinyl alcohol) PVA with different proportions, prepared by the solvent casting method, adding 1% of lithium salt (LiOH). X-ray diffraction (XRD) revealed that increasing the percentage of PVA in relation to PVDF showed a greater non-crystalline nature of the electrolytes and the polymer-salt interactions were analyzed by infrared spectroscopy (FTIR) where the structural characteristics of the polymers used were identified through the spectrum and the changes in bands related to each material. The determination of electrical properties and dielectric behavior were carried out as a function of frequency by complex impedance spectroscopy (EIC), where it was verified that the resistance decreased in the order of $10^3 \Omega$ for the sample with 75% PVA, 25% PVdF and 1 % of LiOH as the most promising result for this research.

Currently, there is a pressing need for alternative energy sources in the global energy matrix, as approximately 80% of the world''s energy consumption is derived from burning fossil fuels [1]. In this context, research in the field of solid-state batteries has been gaining momentum, with sodium titanate emerging as a promising option for ceramic electrolyte production. In this work, lithium-doped sodium titanate was synthed using a sonochemical technique. The titanium isopropoxide was diluted in isopropyl alcohol and mixed with other components on a magnetic stirrer until homogenized, and then subjected to sonication for 15 minutes at a power of 487.5 W (65%). The samples were subsequently dried in an oven for 24 hours at 120 °C. A heat treatment was carried out at 900 °C for one hour. XRD measurements were performed in the non-doped sample and in the sample doped with 1% lithium followed by analysis using Rietveld refinement. In the sample without doping, sodium trititanate ($Na_2Ti_3O_7$) predominated, constituting 84.94% of the composition, along with sodium hexatitanate ($Na_2Ti_6O_{13}$) at 15.06%. In contrast, the sample doped with 1% of Lishowed an increased occurrence of sodium trititanate ($Na_2Ti_3O_7$) at 94.89%, withhexatitanate constituting only 5.11% of the composition.

The synthesis of sodium trititanate through sonochemical means is thus an excellent approach, owing to the high level of purity observed in the resulting samples.

Advances in Materials for Solar Photoelectrochemical Production of Fuels

Oomman K Varghese[1], David Waligo[1], Dhan Rana[1], Bigyan Kandel[1], Jayahansa Napagoda[1], Maggie Paulose[1]

[1]University of Houston (*Department of Physics*)

e-mail: okvarghese@uh.edu

Solar water splitting and carbon dioxide reduction are two leading strategies currently pursued for fuel production aiming at net zero emission. Photovoltaics assisted, thermochemical, photoelectrochemical (PEC) and biomass based processes are primarily explored for achieving this goal. Among these, only PEC water splitting and CO2 reduction involve direct conversion of sunlight to fuels under atmospheric conditions. The PEC technology has not yet been proven commercially viable mainly due to the challenges posed by semiconductors used as photocatalysts. Recently emerged low dimensional materials and heterostructures offer promising pathways for solving these problems. Among various architectures, films of tubular nanostructures vertically aligned on substrates have exceptional properties including their extremely high surface area, improved light absorption and availability of charge carriers in the vicinity of the surfaces/interfaces to carryout redox reactions. In this presentation, we discuss the results of our simulation studies on electromagnetic wave propagation through these nanoscale materials and experiments to develop and characterize these materials for PEC fuel production.

Electrochemical Energy Storage: The Crucial Role of Batteries and Supercapacitors in Modern Technology.

Roberto Manuel Torresi[1]

[1]Universidade de São Paulo (*Instituto de Química*)

e-mail: rtorresi@iq.usp.br

In this presentation, we will discuss the disruptive impacts of metal-ion batteries and electrochemical capacitors on technology and future projections for these technologies, including the development of new materials such as nanostructured silicon (Si). We will also examine the performance of two ionic liquids (ILs), P2225FSI and BMPYRFSI, as electrolytes for Si/polyacrylonitrile (PAN) composite electrodes, which demonstrated promising results with a specific charge capacity of about 1000 mAh g−1 and a coulombic efficiency of nearly 100% after 1000 charge/discharge cycles. We propose LixMn1.8Ti0.2O4@N-doped graphene oxide (x ≤ 1) as a superior positive electrode material for lithium-ion batteries, which showed excellent Li storage performance in organic media due to the incorporation of a conductive carbonaceous matrix. We also studied the Li storage capacity using ionic liquids as electrolyte solvents and found the best response at 40 °C with a specific capacity of 117 mA h g-1 at an applied current density of 1 C. Finally, wewill discuss the benefits and challenges of using ILs as electrolytes in lithium-ion batteries, including their high-rate cycling capabilities and practical applications in extreme environments. ILs offer improved safety, high thermal stability, and low flammability, but challenges such as high viscosity, low conductivity, and obtaining pure and stable ILs must be addressed. Overall, our findings suggest that ILs show great promise for the development of high-performance lithium-ion batteries with enhanced safety and stability.

Interrogating hybrid perovskites from the nano- to the macroscale

Marina S. Leite[1]

[1]University of California, Davis (*Materials Science and Engineering*)

e-mail: mleite@ucdavis.edu

Hybrid organic-inorganic perovskites (HOIPs) are a promising class of material for solar cells. Nevertheless, their long-term stability must be established prior to commercialization. Edisonian, traditional trial-and-error methods for material screening, development, and stability testing are slow considering the vast hyper-parameter space entailing chemical composition and the potential influence of environmental stressors when acted in combination. To overcome this bottleneck towards the identification of stable HOIPs, we realize automated experimentation and machine learning (ML) to gain physical understanding of how these materials' behavior is affected by environmental stressors, suchas relative humidity and temperature. We apply ML models to analyze high throughput, insitu steady-state photoluminescence and predict the changes in CsyFA1−yPb(BrxI1−x)3 perovskites while exposed to relative humidity cycles. We compare linear regression, echo state network, and seasonal auto-regressive integrated moving average with eXogenous regressor algorithms and attain consistent accuracy of >90% for the latter, while following long-term changes for 50 hours. Our accurate time series predictions showcase the promise of ML to mimic non-linear response from a series of hybrid perovskite compositions. At the nanoscale, we implement environmental scanning probe microscopy methods to quantify local changes in the electrical response of these materials. Overall, the suite of characterization methods presented here can be extended to other perovskite families, including Pb-free options.

Novel hybrid perovskites from ab-initio simulations

Nicola Seriani[1]

[1]The Abdus Salam ICTP (*CMSP Section*)

e-mail: nseriani@ictp.it

Hybrid perovskites have shown great potential for photovoltaics, but one of themain issues is that the most active compositions contain lead. For this reason,substantial research efforts are devoted to the substitution of leadwith other elements, also in combination with vacancies. Here, we follow a differentroute, and, supported by ab-initio simulations, we propose that it could be possibleto produce hybrid perovskites where lead is substituted bya small atomic cluster. Simulations predict that some of these compounds can be dynamically stable and can display interesting properties for solar-energy applications.

Radical polymer devices for data and energy storage,and solar cell applications

Giovanni Fanchini[1]

[1]University of Western Ontario (*Physics & Astronomy*)

e-mail: gfanchin@uwo.ca

Organic polyradicals in which each unit is a stable paramagnetic radical that can be reversibly oxidized or reduced, are unique alternatives semiconducting polymers with diamagnetic repeating units that exist only with one state, which are at the basis of most polymer organic electronic devices proposed to date, including bulk-heterojunction organic photovoltaics (OPVs) and field-effect transistors (FETs). While the electrical transport properties in semiconducting polymers can be described by the formation of solitons or polarons along the chain, the electrical conductivity of polyradicals stems the oxidation of a radical site forming a cation, which can oxidize a neighboring neutral site, moving the oxidation even further along the chain in a dynamic redox process known as Marcus electron transfer. This model has enabled the design of redox flow batteries from a large class of polynitroxide radical polymers with stable neutral and cationic states at each repeating unit. Despite recent claims of p-type doping, all such materials have so far fallen short of enabling any electronic devices, such as FETs in which gate modulation and differentiated p-type and n-type transport electrons and holes is necessary. In this talk, we will review our work on electrotunable radical polymers with ambipolar characteristics, in particular poly-(oxo)verdazyls in which each repeating unit may stably exist in the anionic, neutral and cationic configurations. We show that due to the possibility of reversible disproportionation and comproportionation along the polymer chain enables both ambipolar and p-type field effect transistors. Furthermore, the same systems can be utilized in single-layer flow batteries, resistive memory devices and hybrid solar cells.

Undoped and doped vanadium dioxide : synthesis and applications

Mohamed Chaker[1]

[1]Institut National de la Recherche Scientifique (*Energie Matériaux Télécommunications*)

e-mail: mohamed.chaker@inrs.ca

Vanadium dioxide (VO_2) is a "smart" material that exhibits a first-order reversible semiconductor-to-metal transition (SMT) at a temperature of $T_{SMT} \approx 68$ °C. This SMT is associated with a structural transition from a low-temperature (semiconductor) monoclinic phase to a high-temperature (metallic) tetragonal phase and is characterized by drastic changes in VO_2 electrical resistivity and in both its infrared (IR) and terahertz (THz) reflectivity. Furthermore, the SMT properties of VO_2, namely the transition temperature, the sharpness of the transition, the amplitude of the properties modification and the related hysteresis width, can be efficiently tailored through doping with an appropriate concentration of donors and/or acceptors and through a proper control of crystallinity, morphology and stoichiometry of the VO_2 films. In this presentation, we will review our recent achievements on the synthesis, characterization and applications of undoped and doped VO_2 films.

Unravelling the Catalytic Property of Copper-Based Materials for High Electrochemical Conversion of Nitrate Ions to Ammonia

e-mail: gabrfc@umich.edu

NH_3 is an essential raw material in fertilizers, chemical industry, and emerging energy conversion processes. As a dense energy carrier, interest is due to its high amount of hydrogen, high energy density, and easy storage and transportation. The electrochemical reduction of NO_3^- (NO_3RR) is considered an promising technology to generate NH_3, both from an economic and environmental point of view, since: the electrical energy needed in the process can come from renewable sources, for operating in ambient temperature and pressure conditions, the absence of greenhouse gases, the electrochemical conversion of NO_3^- is more efficient in terms of yield rate and faradaic efficiency than N_2 electroreduction. In this talk, we will discuss the NH_3 formation under two different copper-based materials: Cu/Cu_2O electrodeposited composite and Cu_2O nanocubes. Quantification of ammonia produced in the potential range of −0.1 to −0.8 V vs. RHE showed that it is formed in the entire potential range with a maximum Faradaic Efficiency of 87 ± 3 % at −0.4 V and 94 ± 4 % at −0.30 V, for composites and nanocubes, respectively. In situ Raman and FTIR indicate that the reduction of the copper oxides takes place in less negative potentials than the one under which hydroxylamine intermediate is detected, which points out for the importance of oxygen vacancies as active sites for the reaction. In fact, the formation of oxygen vacancies after electrolysis was confirmed by XPS measurements. Microscopy techniques show a modification of the electrode leading to a smoother surface after the electrolysis, which corroborates that the catalytic effect is not related to surface roughening, but to the creation of oxygen vacancies under cathodic potentials. The molecular characterization by DEMS demonstrates that the main pathway to the formation of NH_3 comes from the decomposition of hydroxylamine enhanced by the oxygen vacancies.

2D diamond-like functionalized nanosheets forhydrogen evolution reaction

Bruno Ipaves[1], Pedro Alves da Silva Autreto[1]

[1]Universidade Federal do ABC (*CCNH*)

e-mail: ipavesbruno@gmail.com

Two-dimensional (2D) materials have been widely investigated since the discovery of graphene in 2004 and are excellent candidates for energy storage and catalytic conversion applications. The physical properties of 2D materials can vary considerably depending on the synthesis and functionalization methods, where the origin of all these different properties is still an open question. Accordingly, it is essential to investigate and understand the properties of functionalized 2D structures. In this context, we explored the structural, thermodynamic, dynamic, elastic and electronic properties of diamond-like graphene and diamond-like silicene nanosheets functionalized with distinct types of atoms [1, 2]. We predicted nanosheets with interesting physical properties and potential applications in several fields, including van der Waals heterostructures and thermoelectric devices. In particular, we studied and demonstrated the diamond-like silicene nanosheet functionalized with aluminum atoms is a promising candidate for alkali metal ion batteries, mainly for sodium and potassium ion batteries [3]. Finally, our current results have shown potential for using them as an efficient hydrogen evolution reaction.

2D-materials based nanocomposite thin films for electrodes in aqueous and transparent Na- or K-ion batteries

Aldo José Gorgatti Zarbin[1], Maria Karolina Ramos[1], Ariane Schmidt[1]

[1]Universidade Federal do Paraná (*Departamento de Química*)

e-mail: aldozarbin@ufpr.br

This work presents the preparation of 2D-based thin films materials through on a novel and almost unlimited platform developed in our research group, the so-called liquid-liquid immiscible route (LLIR) [1], and their specific application as electrodes to transparent aqueous sodium- or potassium-ion batteries [2-5]. The LLIR was employed to prepare transparent bi- or tri-components thin films between 2D-materials (MoS_2 or graphene) and carbon nanotubes, copper oxide or Prussian blue analogues, with fine control on the thickness, transparecncy and homogeneity. The evident effect of the nanostructured materials on some superlative properties observed in those electrodes will be demonstrated and discussed based on the structure/properties relationship. Specific capacity as high as 1316 mA h $g^{-1}$for Na-ion aqueous batteries have been found for a MoS_2/Graphene/Cu_2O tri-component nanoarchitected film, at current density of 100 mA g^{-1}[5], which are among the best results presented in literature for this kind of application. Acknowledgments: CNPq, CAPES, INCT Nanocarbono; INCT NanoVida

e-mail: sergio.brochsztain@ufabc.edu.br

We introduce here a novel ligand, N,N'-bis(4-carboxyphenyl)-1,4,5,8-naphthalenediimide (CNDI), which is a suitable compound for the preparation of new materials for the energy sector. The compound was shown to be an excellent ligand for metal organic frameworks (MOFs) and $CsPbBr_3$ perovskites. The compound was synthed in a single step and high yields by using molten imidazole as the solvent. Reaction of CNDI with zinc nitrate or zirconium chloride generated the MOFs CNDI-Zn and CNDI-Zr. The MOFs were characterized by x-ray diffraction, nitrogen adsorption isotherms (BET method) and UV-visible spectroscopy. The presence of micropores was evidenced by BET measurements. The MOFs will be tested for the separation of CO_2 from other gases. CNDI is also an excellent ligand for $CsPbBr_3$ perovskite nanocrystals (NC). Addition of CNDI to a $CsPbBr_3$ NC solution in toluene resulted in strong binding of the imide to the NC surface, resulting in photoluminescence (PL) quenching, which can be attributed to electron transfer (ET) from the $CsPbBr_3$ NC to electron-acceptor CNDI. These results show that CNDI has a great potential for the construction of solar cells.

A secondary source niobium oxide for batteries

Gabriela Cordeiro Silva[1], Michelle Dias Alves Lage[1], Cássia Ribeiro Souza[1], Ana Clara Aparecida Reis[1], Gabriel Túlio Mendes de Alvarenga[1], Sônia Denise Ferreira Rocha[1]

[1]Universidade Federal de Minas Gerais

e-mail: gcsilva25.gc@gmail.com

Batteries that can charge more rapidly and present higher capacity are wanted for electronic devices and electric vehicles. These requirements could be addressed by evolving electrodes that permit fast and safe storage. Niobium-based oxide anodes have shown larger capacity and higher rate capability than commercialized anodes [1]. Niobium oxide, Nb_2O_5, exists in different crystalline polymorphs, which present different electrochemical behavior [1]. In this work, Nb_2O_5hydrates were used as the starting materials to study the calcination temperature effect on the structural properties and electrochemical performance of these polymorphs. The Nb_2O_5hydrates were obtained by extracting Nb from fines that are considered a sub product in the manufacture of FeNb alloys. Before calcination, the Nb_2O_5hydrates were analyzed by TGA. After calcination, all the Nb_2O_5samples were deeply characterized by Raman, FTIR, XRD, SEM and TEM. Their electrochemical performances were tested in cyclic voltammetry measurements. The sample that showed the best structural and electrochemical properties was selected to be used as anode in a Li-ion battery. Therefore, this work not only reports a highly promising anode for fast charge batteries but also purposes the obtention of a niobium-containing product from a secondary source contributing to the improvement and development of urban mining and circular economy.

e-mail: ilnantes@gmail.com

In the water-splitting process, the oxygen evolution reaction constitutes a chokepoint that affects the overpotential. Because of spin constraints, triplet molecular oxygen formation competes with the singlet-mediated formation of hydrogen peroxide. A common strategy to favor spin polarized reactions is the modification of achiral materials with enantiomerically pure chiral ligands. Otherwise, chiral templates, such D and L amino acids and peptides can be used to act as templates for enantiomeric crystal growing of metallic and metal oxide nanoparticles. Recently, we used animal and plant ferritin to assist the synthesis of chiral Co_3O_4quantum dots (QDs) [1]. Natural proteins formed unically by L-α-amino acids can not template the formation of enantiomeric pairs of crystals. We synthesized the enantiomeric tripeptide D- and L-cysteinylhistinylalanine (D- and L-CHA) that efficiently assisted the production of enantiomeric chiromagnetic nanocrystals of Co_3O_4.The bandgap energies obtained for the cobalt oxide are 1.68 and 3.4 eV when D-CHA was the template and 2.17 and 3.48 eV when assisted by L-CHA with bandgap energy differences ($\Delta E = Eg1 - Eg2$) of 1.72 and 1.31 eV, respectively. The X-ray diffraction spectra showed evidenced peaks are indexed to (311), (400), (511) and (440) assigned to Co_3O_4facets. Magnetic circular dichroism evidenced the enantiomeric crystal growing templated by D- and L-CHA. The enantiomeric material was also characterized by high resolution transmission electron microscopy (HRTEM). The next step is the application in the spin-polarized electron transport.

Flash Sinter-Crystallization of $Li_{1.3}Al_{0.3}Ti_{1.7}(PO_4)_3$ for all solid-state batteries

João Vitor Campos[1], Isabela Reis Lavagnini[2], Vinicius Martins Zallocco[3], Ana Candida Martins Rodrigues[1]

[1]Federal University of Sao Carlos (*Departamento de Engenharia de Materiais - DEMa*) , [2]Universidade de São Paulo (*Departamento de Engenharia de Biossistemas*) , [3]Federal University of Sao Carlos

e-mail: joao4.campos@gmail.com

The development of all-solid-state batteries (ASSBs) is a promising technology for replacing the current liquid electrolyte batteries due to their higher energy density, improved safety, and longer lifespan. However, the commercialization of ASSBs is hindered by the low ionic conductivity of solid-state electrolytes and poor electrical contact between the electrolyte and the electrodes. In this study, we explored the use of ***Flash Sinter-Crystallization***(FSC) to accelerate the crystallization process of lithium aluminum titanium phosphate (LATP), a promising solid-state electrolyte. We melted a stoichiometric mix of precursor oxides to obtain a glass precursor of Li_2O - Al_2O_3- TiO_2- $P_2O_5$and processed it into pellets. The pellets were subjected to FSC at low furnace temperature (470 °C) using various current densities (from 10 to 130 mA mm^{-2}) and with an electric field of 200 V cm^{-1}, and the resulting samples were analyzed by Differential Scanning Calorimetry (DSC), ex-situ X-ray diffraction (XRD), and Electrochemical Impedance Spectroscopy (EIS). Our results showed that FSC can enhance the ionic conductivity of LATP by promoting its fast processing. The best results were achieved when a condition of 50 mA $mm^{-2}$was used, with a total ionic conductivity at room temperature of 0.3 mS cm^{-1}(Ea = 0.31 eV) and a bulk conductivity of 1.4 mS cm^{-1}. Furthermore, the FSC process is significantly faster than conventional sinter-crystallization, which typically requires 950 - 1100 °C and 2 hours. In our case, the sinter-crystallization was completed at 470 °C within 300 seconds. Our study demonstrates the effectiveness ofFSC as a fast and efficient technique for the processing of solid-state electrolytes, opening up possibilities for cost-effective solid-state battery production and co-sintering of the cathode with the solid electrolyte.

High capacitance and expanded voltage window of MXene/Nanodiamonds supercapacitors in $AlCl_3$ electrolyte

Murilo H. M. Facure[1,2], Kyle Matthews[3], Ruocun Wang[3], Robert W. Lord[3], Daniel Souza Corrêa[1,2], Yury Gogotsi[3]

[1]Univerdade Federal de São Carlos (*Departamento de Química*), [2]EMBRAPA Instrumentação, [3]Drexel University (*A.J. Drexel Nanomaterials Institute*)

e-mail: murilohmfacure@gmail.com

MXenes have demonstrated excellent performance as constituent materials for supercapacitor electrodes due to their 2D morphology, high electrical conductivity, and large redox-active surface [1]. One of the most outstanding achievements is the capacitance (C) obtained with 2D $Ti_3C_2T_x$ in H_2SO_4 electrolyte, which is related to the surface redox process caused by the intercalation of H^+ between $Ti_3C_2T_x$ layers. The intercalated protons react with the O terminations of MXene and form OH groups, thus changing the Ti oxidation state, which results in the pseudocapacitive behavior [2]. However, a narrow potential window of highly acidic electrolytes (under 1 V) is a limiting feature for many applications. Wider voltage windows are crucial for obtaining supercapacitors with superior energy densities (E), since it is proportional to the square of the voltage (V), according to the formula for a double-layer capacitor: $E = \frac{1}{2}CV^2$ [3]. In this scenario, materials and electrolytes that produce high capacitance and large potential windows are highly sought after. In this work, we used nanodiamonds to pillar the $Ti_3C_2T_x$ structure and obtain superior supercapacitor performance in $AlCl_3$ electrolytes. The superior performance relies on the combination of electrolyte formulation and electrode structure design. The pillaring effect prevents the restacking of MXene layers, reducing diffusion limitations and resulting in a high-rate performance with a capacitance of 235 F/g (561 F/cm^3). The use of 3 M $AlCl_3$ provided protons that contributed to the capacitance obtained and allowed an expansion of the potential window to 1.2 V, due to the lowered activity of water in the electrolyte.

Hydrogen storage properties of the high-entropy alloys derived from the $Ti_xZr_{1-x}CrMnFeNi$ system

Gaspar Andrade[1], Bruno Hessel Silva[2], Guilherme Zepon[2], Ricardo Floriano[1]

[1]Universidade Estadual de Campinas, [2]Universidade Federal de São Carlos

e-mail: g265746@dac.unicamp.br

This study investigated the crystal structure and hydrogen storage properties of the high entropy alloy derivated from the $Ti_xZr_{1-x}CrMnFeNi$ system. The alloys, which had an AB2-type configuration (A: elements forming hydride, B: elements non-forming hydride), were selected by the CALPHAD method [1]. The selected alloys with different at.% of Zr and Ti were evaluated with respect to their microstructure differences and their possible effect on the hydrogen storage properties. The arc-melted Ti-rich alloys showed the presence of BCC and C14 Laves phase in different fractions. On the other hand, the Zr-rich alloys showed the C14 Laves phase, along with a secondary intermetallic NiZr phase. Hydrogen storage properties investigated through pressure-composition-temperature (PCT) absorption and desorption isotherms revealed that the Zr-rich alloy could absorb 1.8 wt% (H/M = 1.2) of hydrogen with fast kinetics at room temperature after a simple heat activation procedure. In contrast, Ti-rich alloys absorbed only 0.2 wt% (H/M = 0.1) with slow kinetics due to their poor activation ability and the possible formation of a titanium oxide layer. The Zr-rich alloys were able to reversibly absorb and fully desorb 1.6 wt% (H/M = 1) of hydrogen. Furthermore, Zr-rich alloys exhibited a very low hydrogen equilibrium pressure in the PCI isotherms. After full hydrogenation at room temperature, the initial metallic C14 Laves phases were converted into their respective Laves phase hydrides in both cases. Under cycling, the fractions of the secondary BCC, NiZr, and C14 Laves phase changed due to the lattice distortion to accommodate the hydrogen atoms. The microstructural analysis, before and after cycling, showed a very well-homogeneous microstructure and good distribution of elements for both Ti and Zr-rich alloys.

e-mail: otavio.lima@ufpe.br

The Anthropocene is marked by the unmistakable trace of human actions in the terrestial environment. Thus, the transition to clean energy alternatives are essential for sustainable human development and the stability of the planet, and green hydrogen is a promising solution to address these challenges [1]. This study aims to develop materials for electrocatalysis of oxygen evolution reaction (OER) using the in situ CO_2laser synthesis. This technique has advantages front conventional film deposition, such as low energy consumption, scalability, and really low time scale, making it possible to produce materials that by other methods take hours, in fractions of seconds [2]. The graphene-based electrode (LIG) was obtained from the laser ablation of polyimide films, and by the same technique, controlling the growth of nanostructured or compact films of cobalt oxide on the LIG' s surface to obtain the LIG-CoO_xmaterial. Different experimental conditions were tested, such as laser power, deposition technique, precursors solutions and concentrations. The electrodes materials were characterized by Raman spectroscopy, X-ray diffractometry, Energy-dispersive X-ray spectroscopy (EDS) and the morphology was analyzed by scanning electron microscopy (SEM). The electrochemical characterizations of bare LIG electrodes in $K_4[Fe(CN)_6]$ 1 mmol.L^{-1}shows peaks separations comparable to commercially available rough carbon electrodes. The OER tests in KOH 1 mol.$L^{-1}$of the LIG-CoO_xreached the threshold current densities of 10 mA.$cm^{-2}$with overpotentials up to 600 mV lower than the bare LIG electrodes in optimal conditions. The oxide layer of the composite electrode also provided great stability over OER, overcoming the problems of swelling, peeling-off and irreversible oxidation of the graphene layers described in the literature [2].

Using solar light in photo-induced processes is attractive since it is a clean and practically limitless energy source. Therefore, research on developing new photocatalysts capable of using this energy has recently been growing. Metal semiconductors have excelled in this field. However, creating materials that utilize the visible radiation component is a contemporary challenge. For this purpose, we discuss the heterojunctions based on titanate nanotubes/carbon nitride [1], bismuth vanadate/tungsten oxide [2], and bismuth niobate/silver nanoparticles [3]. These catalysts were synthesized through microwave-assisted routes, an emergent technique that quickly obtains the desired products with high selectivity, high yields, and low energetic consumption. Thus, several methodological studies can be carried out quickly, allowing the investigation of the ideal synthetic conditions to obtain nanomaterials with controlled morphology and structure. As a result, the establishment of new microwave-assisted synthesis protocols was achieved. These heterojunctions were characterized through several techniques and applied to the photodegradation of organic species and photoelectrochemical generation of H2. A correct band alignment between the heterojunction components is required for these applications. Typically, the photogenerated electrons must flow from the external semiconductor to the host semiconductor; the photogenerated holes must flow from the host to the external semiconductor. This charge separation increases the electrons lifetime by reducing the recombination rates.

Climate change-related disasters have occurred worldwide due to the exhaustive use of fossil fuels. One promising fuel alternative is hydrogen (H_2). While $H_2$is considered a clean fuel, it presents several challenges due to its flammability and low energy density. Inorganic hydrides such as $NaBH_4$can be used as storage systems, but hydrolysis reactions needed to release $H_2$are slow and require catalysts [1]. Niobium (Nb) is a transition metal with a wide range of applications, and most of the reserves are in Brazil (98%), which also accounts for most of the world's production (93%) [2]. Investigations on Nb-catalyzed hydrogen production have used Nb in the form of complexes, nanoparticles and combined with other metals [3]. In this study, we synthesized metal nanocatalysts supported on $Nb_2O_5.nH_2O$ to accelerate the hydrolysis of $NaBH_4$. We reduced a metal precursor (Au, Pd, Ni or Pt) onto $Nb_2O_5.nH_2O$ using a $NaBH_4$solution. The freshly prepared material was then added to a kitasato flask coupled to a burette filled with water. The container was closed, the $NaBH_4$solution was added, and the system was kept under stirring. The amount of H_2released was determined by measuring the water displacement in the burette, and the reaction was monitored until it reached completion. The average rates for H_2production at room temperature were 0.008, 0.051, 0.103, and 1.03 mL H_2 $s^{-1}$for Au (5 mL of H_2), Pd (18 mL of H_2), Ni (37 mL of H_2), and Pt (38 mL of H_2), respectively. We found that PtNPs on $Nb_2O_5.nH_2O$ had a significant catalytic effect and are a promising candidate for further investigations for fuel cell applications.

e-mail: victor.secco@lnnano.cnpem.br

Transition metal dichalcogenides (TMD) materials can generate 2D nanostructures due to their weak van der Waals interaction between monolayers. The $PtSe_2$ synthesis and characterization have not shown as much progress as other TMD like MoX_2 or WX_2 (X=S or Se) possibly due to the difficulty to obtain undamaged monolayers. However, the defects created can also be explored for several applications making $PtSe_2$ an interesting material to be explored. The hydrogen evolution reaction (HER) is one application of interest and catalyst engineering using defects could improve the process' s effectiveness. Here, a new synthesis protocol for $PtSe_2$ nanoparticles through the selenization of previously synthesized Pt nanoparticles was explored. The selenization process was performed in a closed reactor using an excess of Se at high temperatures (400 °C). The excess of Se was removed by solubilization in trioctylphosphine. A hexane solution of butyl-lithium and an ultrasonic bath was used to induce defects. $PtSe_2$ was characterized by HRTEM, EDS chemical analysis, and Pair Distribution Function from Electron Diffraction (ePDF) technique. HRTEM images revealed that after the lithium treatment only the short-range ordering (SRO) was kept showing a high concentration of defects. EDS indicated that Se vacancies are induced in the structure ($PtSe_x$), which was corroborated by XPS results. The new $PtSe_x$ structure presented a Raman Spectroscopy shift on both E_g and A_{1g} peaks and the E_g/A_{1g} intensities ratio was also affected. A new peak appeared in the spectrum assigned to the LA band (Longitudinal Acoustic Mode) from defects. The catalytic experiments showed an overpotential of 330 mV at 10 mA cm^{-2} for the $PtSe_2/PtSe_x$ nanoparticles compared to 90 mV for Pt Nanoparticles. We hope that future $PtSe_x$ defect engineering and catalyst optimization in the electrode could improve the HER performance.

Reactive flash sintering for producing Li-ionconductors

Lílian Menezes de Jesus[1]

[1]Federal University of Sao Carlos（*Department of Physics*）

e-mail: lilian@df.ufscar.br

Flash sintering (FS) [1] consists of applying an electric field while heating a green ceramic sample. This technique has been used to sinter several materials at low temperatures in a matter of seconds, being cost-effective. Recently, FS has been extended to enable the simultaneous synthesis and sintering of ceramics in a derived method called reactive flash sintering (RFS) [2]. Herein, this approach is used for producing two Li-ion conductors: $Li_{0.5}La_{0.5}TiO_3$(LLTO) and $Li_{6.25}Al_{0.25}La_3Zr_2O_{12}$(Al-LLZO). Highly dense single-phase ceramics are obtained in a few seconds, with bulk ionic conductivity of 0.18 and 0.5 mS cm^{-1} for LLTO and Al-LLZO, respectively. Additionally, in-situ synchrotron X-ray diffraction is used to investigate the phase evolution. We show that RFS not only accelerates synthesis and sintering rates but also affects the reaction pathway of these complex oxides. Therefore, the enormous potential of this technique for producing materials with volatile compounds and for stabilizing phases that are not thermodynamically favored upon conventional heating is highlighted.

Discovering compounds that present transition metals with unusual oxidation states or reactive oxygen species (superoxide, peroxide and oxygen-centered radical) is of great scientific and technological interests, as they have key applications as oxidizing agents, catalysts, or reaction intermediates, and can improve the performance of materials for energy conversion and storage.[1]

Here, we use X-ray absorption spectroscopy (XAS) at the oxygen K and metal L_3, M_3or N_3edges of gas-phase $[MO_n]^+$systems (M = transition metal, n= integer) to identify the spectroscopic signatures of oxygen ligands and assign the oxidation state of the metal.[2] Our ion trap is installed at the undulator beamline UE52-PGM at the Berlin synchrotron radiation facility BESSY II operated by the Helmholtz-Zentrum Berlin.[3]

Reactive species, such as oxygen-centered radicals and species containing high-valent transition metals, are analysed in stable conditions in the ground state inside the cryogenic ion trap. This method is here demonstrated to be an important tool to identify the character of oxygen ligands, offering direct access to element specific electronic structures.

Simulating growth of nanostructured materials torelate their microscopic dynamics with their morphologies

Fabio David Alves Aarão Reis[1]

[1]Universidade Federal Fluminense (*Física*)

e-mail: fabioaaraoreis@gmail.com

This presentation summarizes recent works that describe the morphology of growing materials using simulations of kinetic models which were properly designed for each deposition technique. First, we study island growth, coalescence, and initial formation of continuous heteroepitaxial films with a vapor deposition model [1]. A framework is proposed to relate the evolution of the surface roughness and of height correlations with step-edge energy barriers and atom/molecule diffusivities on the substrates. When those barriers are negligible, the roughness shows a maximum as the islands coalesce, as observed in hot-wall CdTe deposition on polyimide substrates and in thermally evaporated perovskite films. Next, using models of electrodeposition with adsorbate diffusion, we show initial compact film formation followed by instability development and dendrite growth [2]. The application to silver electrodeposition on nanoparticulated gold substrates explains the transition from microparticles with (111) facets to pine-tree shaped dendrites which preferentially grow from the corners and edges of those particles [3]. The approach shows that estimates of adatom diffusion coefficients in the electrodeposited structures can be obtained from their sizes and the applied currents. Finally, using a model of sputter deposition, we recently obtained morphologies similar to those of Si films with Ti nanoparticle scaffolds, which were developed for batteries. The multi-institutional Brazilian team currently involved with these modeling approaches is prone to begin other collaborations to describe the growth of novel materials.

This study aims to improve the electrochemical stable potential window (ESPW) of electrochemical double-layer capacitors (EDLCs) while maintaining high capacitance and low series resistance at high discharge rates. The first approach involves the use of inexpensive and non-corrosive lithium sulfate electrolytes, which allow for the application of diverse current collectors and simplify the capacitor assembly process. Electrochemical investigations demonstrate the feasibility of using 1 mol L-1 Li2SO4 aqueous solution for efficient capacitor operation in a wider voltage range, up to 2.0 V. The second approach involves a simple KOH treatment at 800°C of commercial activated carbon, resulting in highly pure carbons with effective surface areas in the range of 1300 m2 g−1 andgravimetric capacitances up to two times that of raw carbon. Re-activated carbons exhibitstable performance for high charge/discharge load in aqueous media at high current densities, achieving capacitance values of 90 F g−1 at 20 A g-1. This research presents apromising technique for improving the performance of EDLCs with potential applications invarious energy storage systems.

There is increasing interest in positive conversion electrodes for Li-S batteries. These batteries offer high specific capacity, low cost, and abundant sulfur. However, they face challenges such as the shuttle effect, where dissolved polysulfides migrate and degrade performance. One solution is to confine sulfur in porous structures [1]. Understanding Li-S battery mechanisms and degradation is vital. X-ray imaging, like CT, reveals morphological changes. In situ and operando experiments combine electrochemical and imaging methods, providing crucial insights for Li-S challenges [2]. In this research, we utilized a mechanochemical synthesis to create a Porous Organic Polymer (MTP-1) that acts as a host material for sulfur, serving as a positive electrode. We then employed microCT or Synchrotron Radiography and EIS simultaneously during cell operation to investigate the structural changes in sulfur and the internal resistance of two different cells: 1) Carbon Black/Sulfur (CB/S8) as the standard, and 2) MTP-1/Sulfur (MTP-1/S8). Analysis of electrochemical data and radiography images revealed superior sulfur handling by MTP-1/S8 in comparison to CB/S8 cells. MTP-1/S8 showed smaller sulfur crystals and favored the growth of alfa-sulfur (Synchrotron), which is more stable. Impedance spectroscopy showed MTP-1/S8 had lower resistance and better sulfur confinement than CB/S8. An interfacial barrier at negative electrode was observed in CB/S8 but not in MTP-1/S8. These findings demonstrate MTP-1's potential as a sulfur host material, improving capacity retention and electrochemical performance in Li-S batteries. Its ability to effectively accommodate sulfur and mitigate the shuttle effect leads to higher specific capacities and improved charge storage. 3D printed systems for laboratory scale-up studies of water splitting

Nycolas dos Santos Galdino[1], Luís Gustavo Marcolan[1,2], Juliano Alves Bonacin[1]

[1]Universidade Estadual de Campinas, [2]Federal Institute of Education, Science and Technology of Amazonas

e-mail: n256959@dac.unicamp.br

Green hydrogen production is essential for more sustainable routes to various sectors of the economy, but requires large investments and scale-up strategies [1]. To reduce production costs, the development of more efficient catalyst is critical, but the performance of laboratory tests does not reflect the same response in larger scale tests. For this reason, it is necessary to perform experiments on energy conversion devices, such as electrolyzer devices [2]. In this regard, the additive manufacturing technique has been widely used to produce electrodes and devices for rapid and inexpensive prototyping [3]. In this work, commercial conductive filament electrodes from Proto-Pasta© were printed by FDM technique and electrochemically characterized for HER and for OER. Then, a modular electrolyzer device was printed with ABS filament and the Proto-Pasta electrodes wirh geometric area of 2.5 cm2 were evaluated to understand the capabilities and limitations of the printed system in H2 production. The polarization curve was obtained at 20 °C with 1.0M KOH electrolyte for current density of 10 mA cm-2 (Ecell = 5.0 V vs. RHE). Mathematical models of electrolizer devices were used to evaluate the activation and ohmic overpotentials constributions. Finally, the application of the printed system for catalyst perfomance studies is proposed.

3D printing-assisted sacrificially templated piezoelectric scaffolds for cell regeneration

e-mail: rafaelras@estudante.ufscar.br

The use of smart materials in tissue engineering has gained attention due to their ability to provide additional functionality and control over cellular fate. Piezoelectric materials offer a paradigm shift by delivering electrical signals to cells through mechanoelectric transduction, aiding tissue regeneration. In this work, we developed piezoelectric scaffolds with two controlled porosity based on gyroid surfaces using polydimethylsiloxane (PDMS) and sodium niobate ($NaNbO_3$). The gyroid-type negative mold was obtained by fused filament fabrication, resulting in a 5-mm-high x 10-mm-dia cylindrical scaffold. The $NaNbO_3$was hydrothermally synthed and incorporated at 30 wt% into PDMS. X-ray diffractograms confirmed the conversion of the initial crystalline structure of $NaNbO_3$to thepiezoelectric orthorhombic perovskite phase. Cubic morphologies with an average of 1.2 μmwere observed after $NaNbO_3$synthesis. Good distribution and dispersion of $NaNbO_3$within the PDMS matrix were confirmed by SEM-FEG and μCT, with the latter also confirming thetrue porosity of the scaffolds: 18 and 63%. Cyclic compression assays showed that increasedporosity led to decreased energy absorption, resulting in decreased damping capacity. After100 cycles, the scaffold bearing the lowest porosity (18%) exhibited the lowest loss of damping capacity (10%), while the 63%-porous showed a reduction of up to 24%. Young''smodulus increased from the absolute value of 0.01 to 0.07 MPa with decreasing porosity,respectively. To summarize, piezoelectric scaffolds were fabricated using PDMS and $NaNbO_3$via 3D printing-assisted sacrificial templating. Porosity was correlated with damping in mechanical compression, providing an important approach to meet the mechanical requirements of scaffolding and the potential to correlate with the electrical output of thepiezoelectric device.

Ab-initio calculations of ion occupancy at interstitials sites in the Prussian Blue framework

Maria Vitória Cavalheiro Issler[1], Cristiano Vicente[1], Cristiani Campos Plá Cid[2], Milton André Tumelero[3], André Avelino Pasa[1]

[1]Universidade Federal de Santa Catarina (*Programa de Pós-Graduação em Física*) , [2]Universidade Federal de Santa Catarina (*Departamento de Física*) , [3]Universidade Federal do Rio Grande do Sul (*Instituto de Física*)

e-mail: mvitoria753@gmail.com

Prussian Blue (PB) and its analogous are fascinating materials, rich in new magneto-optical and electrochemical phenomena, caused mainly by the mixed valence of their iron atoms. The importance of PB also comes from its large interstitial sites in the cubic crystalline structure, which can be empty or filled by alkali metals through redox reactions (intercalation). The great appeal of PB electrodes is the possibility to reach high charge capacities, near to Lithium (Li) batteries, by using rather environment-friendly elements such as Sodium (Na) or Potassium (K), in water-based electrolytes. In this study, Density Functional Theory (DFT) was applied to evaluate the crystalline structure and cell distortions of PB and Prussian White (PW) framework, regarding the presence of Li, Na, K, and Rb atoms. The calculations used the VASP package, plane waves basis and periodic boundary conditions. The exchange-correlation functional was a Perdew-Burke-Ernzerhof (PBE) type, using the Projector-Augmented-Wave (PAW) method to treat the core electrons. A single cell of 56 atoms was calculated and the K space grid was set to have about 64 points. We performed ionic relaxation for PB and PW cubic phase with ion intercalation in three interstitial sites: 8c, 24d, and 32f' site (Wyckoff notation). We observed that independently of the cation on the 8c site, the most stable conformation is a cubic phase, for both PB and PW. The same trend is observed for the 32f' site, where the stabler phase shows rhombohedral symmetry, independently of the cation on the interstitial sites and compound. However, the final phase for cations in the 24d site appears to be compound dependent: for PB, the phase was monoclinic, whereas for PW the phase is always tetragonal, regardless of the ion type. These results could help to understand the presence of crystalline phase transition in charge/discharge of PB and PW as well as the large dispersion of results of charge capacity found in the literature.

Activated biochar as low-cost catalyst for catalytic intermediate co-pyrolysis of waste plastic and biomass

Heryson Tresmann Lopes Arantes[1], Marta Albuquerque Machado[1], Mariana Coelho Santoro[1], Jair Carlos Checon Freitas[1], Célia Machado Ronconi[2], Carolina Bastos Pereira Ligiero[2], Servio Tulio Alves Cassini[1], Igor Carvalho Fontes Sampaio[3], Priscilla Paiva Luz[1]

e-mail: herysontr@gmail.com

The state of Espírito Santo, one of the top producers of coconuts in Brazil, generates a lot of waste from processing and consumption [1]. The use of green coconut pericarp as feedstock in pyrolysis processes was investigated, focusing on turning these residues into valuable products such as bio-oil and catalysts. Waste polystyrene [2] and biochar-based catalysts [3] were employed on catalytic intermediate co-pyrolysis to examine their influence on both the yield and composition of the oil produced. Biochar from intermediate pyrolysis was directly employed as a catalyst, but steam-activated biochars with different activation times from single-step activation were also studied as low-cost catalysts. The properties of the catalysts were characterized by N2 physisorption, SEM, SEM-EDS, XRD, and FTIR analyses. From these techniques, AAEM (particularly K) and O-containing functional groups were identified on both biochar and activated biochars, but the activated ones presented a higher catalytic performance due to their larger surface area (>600m2/g). The results of co-pyrolysis assays showed that biomass and plastic produced a higher yield of oil and that the composition of the oil shifted away from oxygenated compounds [2]. Catalytic co-pyrolysis oils produced more monoaromatics when activated biochar was used as a catalyst, compared to other catalysts reported in the literature [2,3]. This effect was attributed to a synergetic effect between waste polystyrene and activated biochar, which resulted in an oil organic fraction containing up to 60% of xylene in its composition and presenting a HHV of 34.11MJ/kg.

e-mail: elibe.souza@ufpe.br

Hydrogen-carrier molecules are a form of chemical hydrogen storage and have been shown as a promising, safe, clean, and renewable alternative to meet the emerging need to replace fossil fuels emitting CO_2. Since such molecules are resistant to hydrolysis, an efficient catalyst is required. The main properties of Metal-Organic Frameworks (MOFs), such as high porosity, high surface area, as well as chemical and thermal stability, make them promising materials in terms of several relevant applications, including catalysis [1,2]. The biggest problem with metallic nanoparticles (MNPs) is their high surface energy, which causes agglomeration and catalytic deactivation [2]. To prevent the aggregation of MNPs, in this work, the ship-in-bottle method was used to synthe a heterogeneous catalyst composed of a MOF, Zn(Mim) with supported silver nanoparticles (AgNPs). This material was used in the conversion of small molecules, such as NH3BH3 (AB) and NaBH4 (B), into hydrogen. The catalytic activity was verified by comparing with control experiments with AgNPs and support [Zn(Mim)] separately. It was shown that the produced nanocomposite, AgNPs/Zn(Mim), presented catalytic improvement compared to the support and AgNPs . Despite the low silver content (0.18 wt%), interesting results of hydrogen generation rate and rotation frequency were obtained for AB (2286.4 mL.min-1.gcat-1 and 10 molH_2.molcat-1.min-1) and B (3075.41 mL.min-1.gcat-1 and 13.49 molH_2.molcat-1.min-1) hydrogen carriers. Furthermore, the materials were also characterized by SEM, ICP-OES, FTIR, XRD, TGA/DTA, and BET.

e-mail: ill.martins@unila.edu.br

Photochemical process can be used to solar energy storage in the form of hydrogen or low-carbon fuels and are promising systems for chemical energy conversion [1]. For this reason, researches have been carried out to find cheap and efficient materials for these systems. In this context, this work shows the synthesis and characterization of $BiVO_4$(BV), Fe_2O_3(F), and $BiVO_4$-Fe_2O_3(BVF) compounds and analyzes their performance for photoelectrochemical water splitting. The compounds were prepared by precipitation method [2] and subsequently, were deposited, as films, on a conductive FTO (fluorine-doped tin oxide) substrate and tested photoelectrochemically by doctor blade process. The materials were analyzed by X-ray diffraction and the results showed that BV/BVF and F have the crystalline phases of monoclinic and hematite, respectively. Agglomerates of different particles were observed by scanning electron microscopy. The photoelectrochemical tests were carried out between -0.55 and 0.85 V at a scan rate of 50 $mV.s^{-1}$. As results, the current densities obtained for BV and BVF were 6.61 and 14 $\mu A.cm^{-2}$, respectively, up to 1.23 V vs. RHE (reversible hydrogen electrode) under a light source, in contrast to F, without any photoelectrochemical response. For the photoelectrochemical tests, when BV and F were mixed, there was an improvement in the response for hydrogen gas production. This phenomenon occurs because the excited photoelectrons move from the conduction band of the BV to the F, and at the same time, they move from the valence band of the F to the surface of the BV to oxidize the water. Therefore, the results showed that is possible use BV and F for hydrogen production using a photochemical process.

Devices based on the magnetocaloric effect and magnetic phase transition require a source of magnetic field to operate. Permanent magnets remain the primary source of magnetic field in magnetic refrigerators and thermomagnetic motors. However, the performance of these permanent magnets, is evaluated using the Λ_{cool} parameter, developed to evaluate permanent magnets used in refrigeration systems. Therefore, the objective of this work is to perform a parametric and comparative analysis of a C-type and double C-type permanent magnet based on a common parameter to any arrangement of magnets: the figure of merit M*. The analysis was conducted by computational modeling and simulation using a Multiphysics software. Different soft magnetic materials were used in the simulations and the best-performing was used in the magnetic circuit of the C-type permanent magnet to evaluate the action of the magnetic force on a set of gadolinium plates. As a result, it was observed that the soft magnetic material has no significant impact on M*. The same observation can be made regarding the number of gaps, as long as more magnetized blocks are employed in the arrangement. Furthermore, a higher magneto-static force density on a magnetocaloric material can be achieved with larger gaps.

Analysis of Mechanical Parameters Effects onNanofluids Preparation Using 2-step Method

Eliel Wellington Marcelino[1], Sydney Ferreira Santos[1], Humberto Naoyuki Yoshimura[1]

[1]Universidade Federal do ABC

e-mail: eliel.marcelino@ufabc.edu.br

Nanofluids are composed of a base fluid and a fraction of dispersed nanoparticles to enhance the base fluid characteristics such as thermal conductivity, stability, and tribology aspects. The enhancement level of a nanofluid is related to nanoparticle stability, which can be made through chemical or mechanical processes. The chemical stability process is made up of interaction between the base fluid and nanoparticle materials using surfactants, while the mechanical stability process relates to the preparation methods and their characteristics. The 2-step method is the most common nanofluid preparation method, and it is greatly affected by mechanical parameters. The stirring speed, stirring time, and sonication features (exposure time, energy, and amplitude), represent some of the relevant mechanical parameters that may affect the nanofluid stability. In this work, an Al2O3-H2O nanofluid was investigated aiming to depict the mechanical parameters of the nanofluid's stability. For this purpose, zeta potential, dynamic light scattering (DLS), and ultra-violet visible spectroscopy (UV-vis) measurements were performed. The results showed that stirring parameters have a small to medium effect on nanofluid stability, while sonication parameters have a medium to high impact on stability. The stirring parameters tend to decrease the nanoparticle agglomeration level. On the other hand, the sonication parameters improve the level of nanoparticle dispersion. Thus, it was shown that interesting stability levels can be reached by combining both stirring and sonication processes properly.

Assessment of the blends of babassu residual cake and rice husk for briquette production

Chastryane Barros de Sousa Silva[1], João Vitor da Silveira Nunes[1], Pollyana Rodrigues de Carvalho[1], Tassio Lessa do Nascimento[2], Maria Alexsandra de Sousa Rios[3]

e-mail: chastryane@gmail.com

The growing demand for energy and concern about the environmental impacts generated by the excessive use of fossil fuels has reinforced the search for renewable sources, such as biofuels. The present work aimed to evaluate the production of briquettes from the residual cake obtained from the extraction of babassu oil in a mixture with rice husk at proportions of 25%, 50%, and 75%. The authors assessed moisture content (M), volatile matter (VM), ash (A), fixed carbon (FC), and the Higher Heating Value (HHV) of briquette of the residual babassu cake (RBC) and the briquettes of the blends RBC/rice husk (RH). According to the results, the RBC briquette presented 3.60% of M, 85.28% of VM, 3.72% of A, 7.40% of FC, and an HHV of 22.25 MJ/kg. The briquettes of the blends presented the following results - Moisture: 9.99% for RBC(75%)/RH(25%), 9.54% for RBC(50%)/RH(50%), and 8.19% for RBC(25%)/RH(75%); Volatile Matter: 82.71% for RBC(75%)/RH(25%), 79.03% for RBC(50%)/RH(50%), and 75.31% for RBC(25%)/RH(75%); Ash: 6.75% for RBC(75%)/RH(25%), 10.15% for RBC(50%)/RH(50%), and 13.21% for RBC(25%)/RH(75%); Fixed Carbon: 5.50% for RBC(75%)/RH(25%), 1.28% for RBC(50%)/RH(50%), and 3.28% for RBC(25%)/RH(75%), and Higher Calorific Value: 19.22 MJ/kg for RBC(75%)/RH(25%), 17.94 MJ/kg for RBC(50%)/RH(50%), and 17.26 MJ/kg for RBC(25%)/RH(75%). Given the above, it concluded that the residual babassu cake mixed with rice husk has the potential for use as a direct source of energy generation and as a means of improving the performance of other biomass for energy purposes [1].

e-mail: slfavaro@hotmail.com

Search for greater energy efficiency in cooling systems has driven the development of innovative technologies. In this context, solid-state refrigerator stands out as a promising alternative of new thermal exchange device, especially in systems based on i-caloric effects. Despite the great potential, few materials have already been tested for the barocaloric capacity, a specific type of i-caloric effect in response of applying pressure over a material. Therefore, this work aims to evaluate the barocaloric effect in Thermoplastic elastomer (TPE), a widely used material in different areas of the industry, which is capable of being easily processed with different types of additives. The TPE was processed by counter-rotating twin screw extrusion at 60 rpm in a single temperature of 190 °C and characterizedby FTIR, DSC, Young's modulus tests and Shore hardness. Samples were molded in a cylindrical geometry at temperature of 150 °C, and its barocaloric effect were evaluated bya calorimeter with direct measurement of temperature variation, obtaining the value of 11 Kat a pressure of 218 MPa. These values are comparable to the observed in polyurethane and others elastomeric materials [1], thus having a potential for application in refrigeration systems.

Energy storage devices are required for home and vehicle use. Lithium-ion batteries and supercapacitors are widely used, but they are not efficient enough to power large systems and still encounter certain limitations for use in automobiles and pulsed electronic devices. Of many materials, Metal-Organic Frameworks (MOFs) are promising because they form by self-assembly, have low density, high surface area and adjustable pore [1]. To improve electrochemical performance, carbon nanotubes (CNTs) were incorporated into MOFs, chosen for their large surface area and good electrical conductivity [2]. Thus, the composites were generated by the Pickering emulsion method, one from a Zinc Metal-Organic Framework coordinated with benzenecarboxylate, isophthalic acid and benzimidazole ligands, and another composite from a copper MOF coordinated with a benzenecarboxylate, isophthalic acid. After electrochemical analysis, the ZnMOF@CNT composite showed only capacitive behavior, resembling a supercapacitor with 4.94 F/g. The CuMOF@CNT composite showed capacitive and faradic behavior, resembling a pseudocapacitor.

The use of biomass as a precursor in synthesizing higher value-added products has grown in the research scenario focused on green chemistry. In this way, studies focus on treating raw biomass to obtain smaller molecules. When placed in an acid medium, the polymers are broken because the ester group that links the molecules to each other reacts with the medium. This work aims to use HBEA 25 zeolites and sulfonated biochar from coffee to catalyze this depolymerization process. [1][2]Zeolite HBEA 25 had its structure analyzed by SEM and FRX. Therefore, was possible to prove its crystalline structure, and by the BET method, it was possible to assess that it has a specific area of 488 m2/g. Total acidity obtained by TPD-NH3 showed a value of 0.575 mmol/g. Concerning, biochar acidity analysis was carried out by bench titration and obtained concentrations of H+ 0.004810. This sulfonated carbon from coffee grounds showed acidity averaging 0.9611 mmol/g. SEM images and IR analysis confirmed and polycyclic structure. As a future perspective of this project, there is the analysis by HPLC and Capillary Electrophoresis of the reaction made between these materials and the biomass to know the conversion of the response, in addition to looking for new catalytic materials and also to elaborate studies for reuse techniques of these materials. The development of selective and efficient heterogeneous catalytic systems for converting biomass into products of industrial interest is the focus of several studies [1]. In this work, oxides of cerium (Ce100), molybdenum (Mo100) and a mixed oxide based on cerium and molybdenum (CeMo25: with 25% molybdenum) were synthed by the Pechini method, using glycerol as a polyol, and applied in the conversion of fructose. The textural and structural properties of the catalysts were elucidated by FTIR, XRD, TG/DTG, DRS, nitrogen physisorption analysis (BET and BJH), and FTIR using pyridine as a probe molecule. The X-ray diffractograms showed Ce100 had a cubic fluorite-type structure and Mo100 an orthorhombic phase. For CeMo25, the formation of cerium molybdate was identified [2]. CeMo25 showed higher thermal stability and an adequate modulation of acidic sites compared to Mo100. Furthermore, CeMo25 exhibited higher catalytic activity (91.8%) compared to Ce100 (36.8%) already within 3 reaction hours. The mixed oxide exhibited lower formation of insoluble materials and selectivity to products of the retro-aldol route and 5-HMF. The results obtained showed that the main factor influencing fructose conversion is the acid sites present in the catalysts [1]. CeMo25 was used in 4 cycles, with no leaching or significant decrease in the activity observed. All observed characteristics suggest that the synthed oxides are promising for converting biomass into valuable chemicals.

Chemical characterization and evaluation of the electrocatalytic water oxidation reaction promoted by Copper-Prussian blue after termal decomposition

Fiorella Zenaida Fernández Herrera[1], Juliano Alves Bonacin[2] [1]Universidade Estadual de Campinas (*institute of chemistry*) , [2]Universidade Estadual de Campinas

e-mail: f227961@dac.unicamp.br

The following work aims to evaluate the efficiency of different types of Prussian blue catalysts, $[Cu[Fe(CN)_6]_{0.5}*nH_2O]$, in the water oxidation reaction. The evaluated catalysts were prepared by thermal decomposition at different temperatures (60, 140, 400, and 900°C), and XRD, Raman, and FTIR techniques were used for their characterization. To evaluate the performance of the catalysts, their electroactive Area, the Onset value and the Tafel slope were calculated. The results of the chemical characterization showed that the material heated at 60°C and 200°C maintained the crystalline structure and the characteristic bands of a Prussian blue analog, which is related to the cyanide (ν(-CN)) stretching centered at 2100-2200 cm^{-1} in both the Raman and infrared spectra.[1] When the temperature reached 400°C and 900°C, bands characteristic of copper oxide and mixed copper-iron oxide were observed.[2] The catalysts with the highest water content (60 and 200°C) showed lower performance in the water oxidation reaction than the catalysts prepared at 400 and 900°C, which showed the best performance and the highest number of active sites. From these results, we observed that thermal treatment can produce different catalysts using the same precursor. Moreover, the water content of the catalysts modified their performance with respect to the water oxidation reaction. Further studies on the effect of water and surface area on these catalysts under mild conditions are essential to better understand the water oxidation mechanism and to advance the development of new catalysts.

Ionic liquids play a range of applications, with CO_2capture being one of them [1]. Such applications have motivated several studies with the goal of elucidating the behavior of its properties [2]. Ionic liquids based on imidazolium cation have characteristics that aid in the CO_2capture process, which in turn are related to their intermolecular interactions [3]. The objective of this work is to understand how the different substitutions in imidazolium cation affect its intermolecular forces and assist in the capture of CO_2. Molecular dynamics calculations were performed for 14 ionic liquids based on imidazolium cation. RDF, SDF, and MSD calculations were performed in the system structure containing 200 pairs of ionic liquid. After the analysis of the molecular trajectories of these structures, the representative structures of the system were taken and calculations of NCI and DFT were performed. The equilibrium distance between cation and anion remained the same in general. Van der Waals interactions proved to be important for the formation of the ionic pair cluster and interaction free energy proved to be an important driver in the formation of the ionic pair. The correlation between Henry's constant and the value of long-range interaction energies in bulk has shown that they can provide valuable information for the prospection of new IL with CO_2capture potential.

One of the main challenges in the development of photoelectrochemical (PEC) water splitting (WS) devices is the formation of active, stable and low-cost photocathodes. CuO is considered a promising material as a photocathode for PEC reactions, but generally suffers from low stability because the oxidation state of copper is easily changed. Based on our experimental findings utilizing various techniques such as XRD, Raman, and XPS, we demonstrated that CuO was formed on FTO substrate (Fluorine-doped Tin Oxide). Our results by profilometry indicates that the film has a thickness of 200 nm. The UV/Vis spectra combined with Tauc Plot reveal a bandgap value of 2.2 eV. As expected, preliminary tests of PEC measurements demonstrate a photocurrent density of 0.5 mA/cm2 for the pristine CuO film. However, due to its low stability, we employed a strategy involving the deposition of an ultra-thin layer of Si and SiO2 on the surface of film. This was done to minimize the CuO reduction sites to Cu metal and enhance the stability of the film. Additionally, we employed very thin layers of BiVO4 and TiO2 to increase the chemical stability of the films.

e-mail: fiacre229@usp.br

The dependence on the production of energy from fossil fuels such as oil, natural gas and coal generates the emission of large amounts of greenhouse gases, which are spontaneously emitted into the environment, causing dangerous environmental effects such as global warming, which affect the lives of millions of people. One strategy to minimize the environmental crisis is artificial photosynthesis which, through the use of semiconductor materials and sunlight, can reduce CO2 and convert it into products of high chemical value. One of the widely studied semiconductors is Bismuth Vanadate (BiVO4), a material with unique optical, electronic, and structural properties that make it an interesting candidate for the production of solar fuel. In the present work, BiVO4 particles were synthed by the hydrothermal method controlling the pH of the aqueous solution. The XRD and Raman results indicated the formation of a monoclinic phase. The MEV showed that the particle increased with increasing pH, reaching a well-shaped and exposed facete with pH equal to 1. The UV-Vis spectra showed that the pristine BiVO4 have a band gap of approximately 2.3 eV. The photocatalytic CO2 reduction using BiVO4 with well-exposed facet presented unique activity to convert to CO and CH4 products. After 5h of reaction in an aqueous medium, BiVO4 /pH 1 produced 0.213 µmol and 0.022 µmol of CO and CH4, respectively. In order to improve the photocatalytic activity, Ruthenium nanoparticles were deposited on the surface by the chemical impregnation method in different concentrations, as a result it was obtained that for BiVO 4 /0.05%wt Ru/pH 1, the amounts of CO and CH4 were 0.462 µmol and 0.132 µmol, respectively, showing a significant increase at 117% CO and at 500% CH4, effectively increasing their photocatalytic activity.(1,2)

Development of SiO2-BaF2 anti-reflective coatingapplied as solar glass

Ramon Carvalho[1], Cristian Dias Fernandes[2], Pedro Lovato Gomes Jardim[2], Mário Lúcio Moreira[2]

[1]Universidade Federal de Pelotas (*Programa de Pós-graduação em Física*) , [2]Universidade Federal de Pelotas

e-mail: ramondadaltocarvalho@gmail.com

In this study, we present a methodology for developing a broadband antireflective coating deposited on a glass substrate, which incorporates porosity in the films. We evaluate the film's application as solar glass in covering a monocrystalline silicon solar cell [1], and we examine the increase in transmittance of the film compared to the glass substrate. Additionally, we investigate the influence of the films on the photovoltaic parameters, such as the fill factor (FF) and power conversion efficiency (PCE). We synthed SiO2-BaF2 by sol-gel and dip-coating deposition, where we varied withdrawal from 0.5 mm/s to 4 mm/s, followed by thermal treatment at 100°C for 1 h. We characterized the films by analyzing their transmittance and reflectance spectroscopy, and scanning electron microscopy. We also performed electrical characterization of the solar cell covered with the different films and the glass substrate to obtain the parameters of short circuit current density (Jsc) andopen circuit potential (Voc), which allowed us to determine the FF and PCE. The results of transmittance in the visible region (400-800 nm) show that the films with different withdrawal had the following transmittance: 0.5 mm/s with 92.9%, 1 mm/s with 93.9%, 2 mm/s with 95.9%, 3 mm/s with 95.7%, 4 mm/s with 96.0%, and the glass substrate with 91.8%. The film shows an approximate 4.5% improvement in transmittance in the visible region compared to the glass substrate. The increase occurred due to the insertion of porosity, which is related to the in-situ formation of hydrofluoric acid (HF). Porosity contributed to the graded index of refraction in the SiO2-BaF2 film, and these conditions influenced reflectance suppression. And we evaluated the PCE and FF of the solar cell with the device covered with the glass substrate and with the best transmittance film.

Development of sputtered BiVO4-CuO Tandem cells for bias-free solar water splitting.

Renato Vitalino Gonçalves[1], Lucas Gabriel Rabelo[2], Washington Santa Rosa[3]

[1]Universidade de São Paulo (*Sao Carlos Institute of Physics*) , [2]Instituto de Física de SãoCarlos - USP, [3] Instituto de Física de São Carlos da Universidade de São Paulo (*FCM*)

e-mail: rgoncalves@ifsc.usp.br

Photoelectrochemical (PEC) water splitting is a promising technique for converting solar energy into green hydrogen, addressing global energy and environmental issues[1].Developing Tandem PEC deviceswith stable metal oxides has recently attracted attention for cleaving H_2O moleculesinto H_2 using only solar energy[2]. Herein, $BiVO_4/FeNiO_x$ and CuO photoelectrodes were synthesized via magnetron sputtering to perform oxygen and hydrogen evolution reactions (OER and HER, respectively) in a simple Tandem PEC cell. Our $BiVO_4/FeNiO_x$ photoanode showed excellent PEC performance and chemical stability for OER, achieving a photocurrent density of +1.22mAcm-2 and a charge transfer efficiency of 96% at the water oxidation potential. In contrast, the all-sputtered CuO photocathode exhibited a modest PEC performance for HER, with an onset potential at 1.03V vs. RHE (reversible hydrogen electrode) and photocurrent density of -0.35mA.cm-2 at +0.40V vs. RHE. In this work, we also investigated the energy diagrams of the photoelectrodes under working conditions for PEC water splitting. Our results demonstrated that the photogenerated holes (electrons) at the $BiVO_4/FeNiO_x$ (CuO) film have enough energy to perform the OER (HER) without external bias. Conclusively, our $BiVO_4/FeNiO_x$-CuO Tandem PEC cell produced a stable operating photocurrent density of ~50μA.cm-2 under zero-bias and AM 1.5G illumination for at least 1000 seconds, evidencing the occurrence of bias-free solar water splitting reactions.

The development of solar energy technologies is crucial to achieving the sustainable development of human society. To solve the problems of environmental pollution and fossil fuel shortage, recent technologies have incorporated innovative solutions [1, 2]. This study aims to investigate a Tandem cell composed of thin films of semiconductor materials, BiVO4 and LaFeO3, to produce solar H2 from water and sunlight without external polarization. The films were deposited on fluorine-doped tin oxide (FTO) substrates using RF-Sputtering techniques and ceramic targets processed by the research group [2,3]. XRD and Raman spectroscopy confirmed the monoclinic and pure phases of the LaFeO3 and BiVO4 films, respectively. The thickness of the films was determined by profilometry, indicating 80 nm for BiVO4 and 100 nm for LaFeO3 films. UV/Vis spectra demonstrated a bandgap value of 2.5 eV for BiVO4 and 2.1eV for LaFeO3. PEC measurements showed a photocurrent density of 1.1 mA/cm2 for BiVO4 and 100 □A/cm2 for LaFeO3 films. Therefore, the low photocurrent density of LaFeO3 led to the deposition of a layer of BiVO4 over the LaFeO3 film to increase the photocurrent density. Furthermore, a layer of NiFe was deposited over BiVO4 to increase its stability. These results provide crucial information about the properties and performance of BiVO4 and LaFeO3 films and suggest promising applications in solar energy conversion such as tandem cell systems.

Diamond-like silicene nanosheets surface-doped:physical properties and potential applications

Bruno Ipaves[1], João Francisco Justo[2], Lucy Vitória Credidio Assali[1]

[1]Instituto de Física da Universidade de São Paulo, [2]Escola Politécnica de Universidade deSão Paulo

e-mail: ipavesbruno@usp.br

Two-dimensional (2D) materials have been widely investigated since graphene was synthed in 2004. One of the most fascinating characteristics of these materials is the possibility of doping and/or functionalizing them with several and different kinds of atoms, making their properties vary considerably [1]. Consequently, it is of great interest to investigate and understand the physical properties of doped 2D structures since they are potential candidates for applications in several and interesting areas. Whithin this panorama, we explored the properties of diamond-like silicene nanosheets, namely bilayers and trilayers, functionalized with boron, nitrogen, aluminum and phosphorus atoms [2]. In particular, the three-layer doped silicon systems present scarce literature and, in this work, we found four novel nanosheet systems, named ABC-Si_4B_2, ABC-Si_4Al_2, AA'A''-Si_4P_2, and ABC-Si_4P_2, with interesting physical properties and promising applications. Our investigation provides these systems' structural, thermodynamic, dynamic, elastic and electronic properties. Analyzing the electronic structure of these materials, we found two distinct groups of dynamically stable nanosheets: metallic and semiconductors systems. Furthermore, we discuss the possibility of using these nanosheets in alkali metal ion batteries (AMIBs), van der Waals heterostructures, UV light devices and thermoelectric materials. Finally, we already demonstrate that the ABC-Si_4Al_2system is a promising candidate for AMIBs anodes, mainly for sodium and potassium ion batteries [3].

In this study, the effect of the application of microporous zeolites with different pore systems (one-dimensional ZSM-23, two-dimensional ferrierite and three-dimensional LTA) and physical-chemical properties in relation to their hierarchical zeolites (micro-mesoporous) derived from the adsorption process of CO_2at 30 °C under atmospheric pressure. The zeolites were characterized by X-ray diffraction, energy dispersive X-ray, nitrogen adsorption-desorption and temperature-programmed desorption of carbon dioxide. The synthesized microporous zeolites (ZSM-23, FER and LTA) presented physicochemical characteristics similar to those described for their structures in the literature. The post-synthesis treatment via desilication (in the case of zeolites ZSM-23 and FER) and the use of sodium glutamate (in the synthesis of zeolite LTA-Glut), allowed obtaining hierarchical zeolites (micro-mesoporous). The hierarchical zeolites showed a higher CO_2adsorption capacity (between 0.3 $mg_{CO2}/g_{Adsorbent}$to 13.7 $mg_{CO2}/g_{Adsorbent}$) than the microporous zeolites (between 0.6 $mg_{CO2}/g_{Adsorbent}$and 10.4 $mg_{CO2}/g_{Adsorbent}$) due to the simultaneous action of their higher area and volume, concentration and strength of the basic sites and the presence of mesoporosity, with a strong dependence on the increase in the adsorption capacity for zeolites with more open pore systems (LTA three-dimensional pore system >FER two-dimensional pore system >ZSM-23 one-dimensional pore system).

Solid oxide electrochemical reactors are a promising alternative for challenging chemical reactions, such as oxidative coupling of methane (OCM)[1], which convert methane to C^{2+}products. Cerium oxide is a commonly studied oxide membrane material for its high ionic conductivity in the temperature range ideal for conversion reactions (600-900°C), particularly when doped with rare earth cations like Gd, Sm, or La. Recent studies have shown $La_2Ce_2O_7$as a promising OCM catalyst[2]. This study investigates the structural properties of $La_xCe_{(1-x)}O_{2(1-x/2)}$thin films, prepared using pulsed laser deposition, with varying stoichiometry. XRD results indicate textured film growth with preferential [100] orientation of cubic crystalline fluorite for low La content (x≤0.5), while x>0.5 had a random orientation. La doping expanded the fluorite structure, increasing lattice parameters from 5.42 Å for x=0 to 5.69 Å for x=0.7. UV-Raman spectroscopy showed that La content x=10 caused a more pronounced balance between $Ce^{4+}$and Ce^{3+}than pure ceria samples. Impedance revealed a direct relationship between La content and resistance, indicating lower resistance with lower La content. These findings could lead to using Ce-La oxides thinfilms as catalysts for OCM in electrochemical reactors based on ceria.

Electrocatalytic activity of CoFe Prussian blue analogues and their calcination product towards the oxygen evolution reaction in neutral and alkaline media

Evandro Datti[1], Juliano Alves Bonacin[1]

[1]Universidade Estadual de Campinas

e-mail: e170698@dac.unicamp.br

Water splitting is one of the most promising methods to produce renewable energy, nevertheless the oxygen evolution reaction (OER) involves a complex multistep proton-coupled electron transfer process, meaning this half reaction is kinetically sluggish and requires a large overpotential. Therefore, an electrocatalyst must be used to overcome the thermodynamics and kinetics requirements [1,2]. Prussian blue analogues (PBA) are considered remarkable catalysts for water oxidation in neutral medium and they have attracted increasing attention. In addition, PBA can also be used as a template to generate oxides by calcination, like the bimetallic spinel oxides which have emerged as outstanding candidates for oxygen evolution reaction catalysts [1,3]. Thus, this work aimed to investigate the electrocatalytic activity of $Co_3[Fe(CN)_6]_2$ and $Co_4[Fe(CN)_6]_2$ films and the oxides derived from their calcination at 500°C towards OER in neutral and alkaline media.To carry out this study, CoFe Prussian blue analogues films were deposited on fluorine doped tin oxide (FTO) coated glass by using different methods (drop-casting, electrochemical and spray coating). These films were afterward calcined at 500°C and electrochemical measurements were made with all of them in 0.5 M KNO3, 0.1 M KOH and 1 M KOH solutions. The results demonstrated that the calcined films are better catalysts for oxygen evolution reaction than CoFe PBA. Besides, the oxides showed to be significantly more efficient in alkaline medium and their electrocatalytic activity is affected by the deposition method employed to prepare them.

Electrochemical characterization and structuralanalysis of $CaSr_xCu_{3-x}Ti_4O_{12}$ ceramic oxide for supercapacitor applications

Hussein Abdul Karim Moussa[1], Johan Alexander Cortes Suarez[1], Márcio Sousa Góes[1]

[1]Universidade Federal da Integração Latino-Americana (*Instituto Latino-Americano de Ciências da Vida e da Natureza (ILACVN)*)

e-mail: hak.moussa.2018@unila.edu.br

In this work, we present a comprehensive analysis of the electrochemical and structural properties of $CaSr_xCu_{3-x}Ti_4O_{12}$(x = 0.00, 0.15, 0.30, 3.00) (CSCTO) ceramic oxide for its potential use as a supercapacitor material [1]. The CSCTO samples were synthesized using a solid-state reaction method and characterized using various techniques such as X-ray diffraction (XRD), scanning electron microscopy, and electrochemical measurements. The CSCTO samples were deposited as films on an FTO (fluorine-doped tin oxide) substrate, and the electrochemical performances were investigated using cyclic voltammetry. The crystal structure and phase composition of the ceramic oxide samples were analyzed using XRD. All samples had a perovskite-like crystal structure. The CCTO sample (x = 0.00) exhibited only the $CaCu_3Ti_4O_{12}$with a cubic phase, while the SCTO sample (x = 3.00) showed the $Sr_{0.75}Ca_{0.25}TiO_3$with a tetragonal phase, which is in agreement with previous studies [2]. The CCTO 0.15Sr and CCTO 0.30Sr samples presented a mixture of CCTO and SCTO phases with slight stoichiometric variations. The specific capacitance values were determined using cyclic voltammetry, and the results showed that the CCTO 0.15Sr sample exhibited the highest specific capacitance of 22.11 mF g^{-1}at a scan rate of 100 mV s^{-1}, followed by CCTO with 5.77 mF g^{-1}, CCTO 0.30Sr with 7.4 mF g^{-1}, and SCTO with 0.8 mF g^{-1}.

e-mail: debora.neves@ufabc.edu.br

Rapid population growth and the effects of urbanization urgently demand new technologies for efficient and sustainable energy storage and conversion in order to replace energy sources from fossil fuels. Thinking about this scenario, fuel cells emerge as a promising alternative due to their high efficiency and flexibility regarding the use of fuels, in addition to low or no CO_2emissions. Solid oxide cells have greater chemical stability and greater durability when compared to other types of cells, but one of their limitations is their operating temperature (800 - 1000 °C), to solve this limitation the next generation of SOFC passed to study proton cells that have a high conversion rate at intermediate temperatures (500 - 700 ºC). Among the most studied solid oxide electrolytes are barium zirconate cerate perovskites, which is an ABO_3type perovskite[1]. In addition to the study of new compositions, there are new designs of materials and structures that allow optimizing the operating temperature. As the thickness of the electrolyte is a determining factor in the performance of the cell, since its ohmic resistance is directly related to electrolyte thickness, the advancement in cell technology has progressed towards smaller and smaller thicknesses using more advanced deposition techniques such as PLD (Pulsed Laser Deposition) [2]. In this work the aim is to compare and characterize by X-ray diffraction (XRD), scanning electron microscopy (SEM) and impedance spectroscopy (EIS), sintered pellets and thin film deposited by PLD.

Electrochemical properties of carbon-supported palladium nanostructures with different metallicloadings

Elizabeth Leal Garcia de Paiva[1], Eduardo Gonçalves Ciapina[2], Roberto Zenhei Nakazato[2]

[1]Universidade Estadual Paulista/guaratinguetá (*Química e Energia*) , [2]Universidade Estadual Paulista/guaratinguetá

e-mail: elizabeth.paiva@unesp.br

High-surface area carbon-supported palladium (Pd/C) nanostructures are of great importance for electrochemical energy conversion and storage devices, such as fuel cells, water electrolyzers, and electrochemical sensors. However, the influence of the amount of metal anchored to the support on the electrochemical properties is not yet understood [1]. In this work, the electrochemical response in 0.1 M H2SO4 of Pd/C electrocatalysts (prepared previously by a colloidal synthesis method) containing different mass fractions of metal over carbon was investigated using the cyclic voltammetry technique. The results showed that the amount of palladium oxide (PdO) formed on the Pd/C electrodes clearly depends on the metal-to-carbon ratio, where an increase in the metal mass fraction leads toa decrease in the coverage of PdO. In contrast, the ratio between the amount of hydrogen desorbed and adsorbed (Hdes/Had) from the electrode was found to increase with the metal loading. A ratio (Hdes/Had) < 1 can be attributed to a spillover o Had towards the carbon phase [2]. Therefore, our results suggest that such a spillover effect decreases with the increase in the metal loading likely due to a reduced metal-metal interparticle distance expected to occur as the metal loading is increased.

Supported-metal catalysts are used in the chemical industry from fine chemical production to petrochemicals and consist of metallic particles dispersed on the surface of a metallic oxide support with different geometrical formats [1-3]. Catalysts with metallic active phases are used for reforming reactions since they have a high capacity to cleave C-C bonds, an essential step for high conversion of hydrocarbons into hydrogen rich syngas. Techniques for catalysts processing from a predefined support usually employ three fundamental steps: increase of the surface area by chemical route; impregnation of the active phase; and heat treatment. Each step directly influences either chemical composition or electronic configuration of the active phases, where the latter property plays a key role on the catalyst activity. In this work, X-ray photoelectron spectroscopy was used to investigate the chemical properties of alumina supported metal catalysts, e.g., Ni, Pt, Cu and Y, obtained by chemical and physical methods. The chemical composition and electronic states were evaluated from measurements of high-resolution spectra for the following chemical states: Al 2p, Ni 2p, Pt 4f, Pt 4d, Cu 2p, Y 3d, O 1s and C 1s. The valence band was also analyzed from the density of states measured between -10 and 30 eV. Results show that the preparation methods as well as the thermodynamic and chemical conditions are fundamental steps to the growing of catalytic surfaces with a strong signal of electronic states at the zero of the energy scale, which is assigned to the valence of the non-oxidized metallic particles.

Enhanced Electrochemical Properties of Screen-Printed Electrodes with Polyaniline-based Hybrid Materials with Reduced Graphene Oxide for applications in Biofuel Cells

Milton Alexandre Cardoso[1], José Hérelis Simão Carnauba[2], Fábio Ruiz Simões[2] [1]Federal University of Sao Paulo (*Marine sciences*), [2]Federal University of Sao Paulo*e-mail:*

milton.alexandre@unifesp.br

Hybrid materials of polyaniline (PAni) with 2% graphite-based materials, such as graphene oxide reduced with ascorbic acid (rGO AA) and graphene oxide reduced with hydrazine sulfate (rGO SH), were fabricated and applied to hand-made screen-printed electrodes (SPE)[1] as modified anodes for use in biofuel cells with ***Saccharomyces cerevisiae***[2]. The materials were characterized using scanning electron microscopy (SEM), Raman spectroscopy, and attenuated total reflectance Fourier transform infrared spectroscopy (ATR-FTIR), followed by evaluation through cyclic voltammetry (CV) and electrochemical impedance spectroscopy (EIS). The bioelectrochemical system was characterized and studied using CV, EIS, and polarization curve. Results showed that PAni-rGO AA and PAni-rGO SH increased the current intensity in CV results, maintained the PAni voltammogramprofile, and reduced charge transfer resistance (EIE). However, the current intensity obtained was higher for the electrode modified with PAni-rGO SH. The SPE/PAni-rGO SHwas successfully applied to bicompartimental biofuel cells, obtaining electrical current from the ***S. cerevisiae***.

Enhancing hydrogen storage capabilities of graphene oxide via Mg based nanostructures

Daniel de Martini Rivera Ferreira[1], Augusto Pietro Rosa Preguiça[1], Ana Champi[1], Pedro Paulo de Mello Venezuela[2], Lucas Almeida Miranda Barreto[1]

[1]Universidade Federal do ABC, [2]Universidade Federal Fluminense (*fisica*)

e-mail: ddmrferreira@gmail.com

The global search for sustainable and renewable energy sources has gained significant momentum in recent years due to increasing concerns about climate change and the need to transition towards a low-carbon economy. Hydrogen has shown up as a great alternative, and one example is its use in fuel cells, which has water as a chemical green product. Many industries, like aerospace and automotive, are heading in the direction of the Hydrogen Economy and the electrification of these sectors is becoming increasingly inevitable. One of the challenges is, however, how to store H_2 molecules for later usage. Therefore, designing materials to capture those molecules properly is a great area of interest. In this work, we study Hydrogen adsorption on graphene oxide (GO) decorated with Mg (GO-Mg) from first principles calculations via Density Functional Theory (DFT). Functionals with Van der Waals (VdW) interaction corrections were used to take them into account. To model GO we used Hydroxyl and Epoxy functional groups which, when in contact with the Mg atom, originate different nanostructures with interesting structural and electronic properties. We used an energy based approach to calculate the stability of each GO-Mg nanostructures and analyzed the charge distributions on the systems. We found that Mg modifies the GO structure and is energetically favorable to form. Furthermore, the ability to capture H_2 molecules is enhanced in GO-Mg compared to pure GO. Adsorption energies were enhanced from 0.08 eV to 0.26 eV, now being in the desired range of 0.15 - 0.3 eV, in order to release the molecules from storage in ambient temperature without needing too much energy. The results indicate that GO-Mg has potential applications in hydrogen storage.

Environmentally friendlier perovskite nanocrystals for photovoltaic applications

Calink Indiara do Livramento dos Santos[1], Maria Zilda Oliveira[2,1], Giovanna Machado[1]

[1]Centro de tecnologias estratégicas do Nordeste, [2]Universidade Federal de Pernambuco (*Centro de Ciências Exatas e da Natureza*)

e-mail: calinkindiara@hotmail.com

The class of materials with perovskite crystalline structure has excelled in the fields of energy conversion since its unique properties have enabled the development as optoelectronic materials with unprecedented speed, however, the research on more environmentally friendly methods for their synthesis, and on less toxic materials of enhanced stability are still in the early stages. [1] Among the improvement possibilities, potential "greener" alternative solvents are an appealing direction for enabling industrial processes.[2] We proposed the synthesis of perovskite NCs investigating the compatibility of "greener" solvents in established CsPbBr3 perovskite NCs synthesis. Water and limonene were used as solvents during the procedure, and LARP (Ligand-assisted reprecipitation) wasused as methodology. Influences of changes in procedure and components, such as surfaceligands, precursors molar ratios and temperature use, in obtained materials were evaluated,as well as ways for deposition in TiO2 substrates, focusing in application in energy conversion.

Sustainable feedstocks are an alternative to supply society's energy demands without causing any environmental harms [1]. Approximately 1.6 billion tons of food are discarded worldwide every year which is often dumped in landfills causing environmental problems [2]. Thus, the aim of this work is to develop an efficient enzymatic catalyst for the degradation of domestic food waste with energy purposes. Hydrolytic enzymes were selected through tests varying the concentration of their solutions between 8 and 30 U/mL to compose a pool for immobilization via adsorption on magnetic biochar. The reactions were carried out at 40ºC under agitation at 120 rpm and tap water. The samples consistedof food waste in the proportion of 65% carbohydrates, 17% lipids and 18% proteins. The determination of lipase (Rhizopus niveus) activity was performed by acidity determination method by titration with NaOH. To evaluate the activity of cellulase (Aspergillus aculeatus), pectin lyase (mix of Aspergillus and Trichoderma reesei) and glucoamylase (Aspergillus niger), the 3,5-dinitrosalicylic acid method was applied. Celullase showed the highest activity (97 g/L of reducing sugars) in comparison with blank (20 g/L). Pectin lyase and glucoamylase also presented higher concentrations of reducing sugars (41 g/L and 47 g/L, respectively). Lipase activity achieved an acidity value of 78% in the oily phase against the blank (20%). The same enzyme in the aqueous phase generated an increase of 196% in the concentration of fatty acids. In addition, no pH variation was observed during the reaction. The free enzymes demonstrated excellent activity in the degradation of kitchen waste even though they were in a medium with tap water and no pH control. The next step is to immobilize the enzymatic pool on magnetic biochar and evaluate its activity.

Evaluation of nanostructured Co-Prussian Blue as a potential catalyst for Water Oxidation Reaction

Gabriel Rodrigues Alvarenga[1], Juliano Alves Bonacin[2]

[1]Universidade Estadual de Campinas (*Instituto de Química*) , [2]Universidade Estadual de Campinas

e-mail: g172422@dac.unicamp.br

It is widely known that humankind' s current energy matrix is sustained by fossil fuels due to their relatively lower prices in relation to cleaner energy sources, but the ever-growing effects of the carbon emissions in global warming are the major incentive to maneuver towards more sustainable and efficient alternatives. A potential solution for this predicament is hydrogen gas (H_2). Still, since only a very small portion comes from renewable sources, many researchers are trying to concoct cheaper catalysts for Water Splitting. Therefore, this work aims to develop an optimally nanostructured Cobalt Prussian Blue Analogue (CoPBA) catalyst for Water Oxidation Reaction. Carrying out a coprecipitation method using potassium hexacyanocobaltate(III) (0.6 mol) and cobalt(II) acetate (0.4 mol), we have been able to consistently prepare multiple different morphologies modifying specific parameters (Fig. 1) to obtain even smaller structures, such as i) Addition of sodium citrate (0.9 mmol) as coordination agent ii) Usage of CoPBA seed (10 mg) iii) Increasing aging time, ranging from 3 hours to 7 days iv) Reacting it with 5 mL of ammonium hydroxide (NH_4OH) to prepare hollow nanocubes. The characterization of the CoPBAs was done via spectroscopic (FTIR, Raman, and UV-Vis) and diffractometric (XRD) techniques and we are currently evaluating its catalytic behavior using various electrochemical methods (CV, LSV, SECV, and others). Initial overpotential (η), Onset potential, and Tafel slope (A) comparations have shown noticeable differences between amorphous CoPBA (η = 1456 mV, Onset = 1834 mV and A = 228 mV.dec) and its nanostructured counterparts: CoPBA-citrate (η = 1409 mV, Onset = 1722 mV and A = 155 mV.dec^{-1}), CoPBA-Seed (η = 1511 mV, Onset = 1781 mV and A = 153 mV.dec^{-1}) and Hollow-CoPBA (η = 1409 mV, Onset = 1722 mV and A = 155 mV.dec^{-1}).

EVALUATION OF THE BAROCALORIC EFFECT INMETAL-ORGANIC FRAMEWORK (MOF) OF THE PEROVSKITE TYPE - NICKEL

Current refrigeration systems use refrigerant gases as their working principle, which are responsible for a large part of the greenhouse effect. The development of technologies with greater energy efficiency and aimed at reducing environmental impacts has led to the search for new materials to replace these harmful gases. The use of solid refrigerants that have i-caloric effects is an alternative. The effect is the change in temperature and entropy of the material when exposed to external some force field. The barocaloric effect (σb-CE) is characterized by the heating or cooling of materials when subjected to isostatic tension (pressure) variation, in addition, the σb-CE effect is highlighted because it has been little explored, but simple to perform, due to its practicality. of the application of mechanical stress compared to a magnetic or electric field [1]. Metal organic frameworks (MOFs) are an emerging class of porous materials, prepared through several synthetic routes, through coordination reactions between metal ions and/or clusters with organic ligands. Perovskite-type MOFs have aroused great interest due to their ferroelectricity and ferromagnetism properties. Furthermore, some organic-inorganic hybrid perovskites showed a high barocaloric effect that aroused interest in the study of these materials [1]. Thus, the study aimed to synthesize, characterize physico-chemically and investigate the σb-CE of nickel perovskite MOFs. After X-ray Diffraction (XRD) and Scanning Electron Microscopy (SEM) analysis, the sample synthesis proved to be efficient, producing well-structured MOFs. Furthermore, with the direct measurements of adiabatic temperature difference, the sample showed a high value of ΔTs = 3.3 K, showing its potential for application in solid refrigeration.

e-mail: slfavaro@hotmail.com

Search for greater energy efficiency in cooling systems has driven the development of innovative technologies. In this context, there has been a significant increase in the search for new materials that exhibit the barocaloric (BC) effect. We can highlight for example the colossal barocaloric effect discovered in the higher n-alkanes (adiabatic temperature changes for eicosane (C20H42) as 38 K up to 218 MPa and predicted colossal isothermal entropy changes higher than 900 J kg-1K-1). Another important discovery was the mechanocaloric compressive effect on cork (tensions up to 218 MPa with giant values of temperature change up to 13.6 K and entropy change up to 101.3 J kg-1 K-1) because it is a natural, renewable and sustainable material. Driven by these discoveries, mainly the manifestation of the mechanocaloric compressive effect (which is the general case of the barocaloric effect, characterized with the application of a hydrostatic pressure) in a natural materials, this work aimed to investigate the BC in corn oil and coconut oil, a commercially available, highly processed, low cost material in addition to being a natural, renewable and sustainable material. To measure the BC effect, 2.5ml of the oil was used, placed in a cavity with a diameter of 12 mm. The BC effect was measured directly using homemade equipment, where the temperature variation of the specimens was measured after a compression and decompression procedure. By these measurements was obtained a maximum temperature variation of ~14 K at a pressure of 218 MPa at 293 K for corn oil and ~13.7 K at a pressure of 218 MPa at 303 K for coconut oil, presenting values comparable to that observed in the literartura. The two investigated oils have the potential to be applied in cooling systems using the BC effect principle.

Natural rubber produced from ***Hevea brasiliensis*** has played a crucial role in the development of Brazil''s economy since the early 19th century. Nowadays, Brazil remains a significant producer of natural rubber, with the majority of its output being used for domestic consumption. The country's importance in the global rubber market has also been revived by the growing demand for sustainable and eco-friendly products. In parallel, solid-state refrigeration based on barocaloric effect has garnered global attention as a promising eco-friendly substitute for conventional vapor-compression refrigeration. In our work, we demonstrate for the first time giant and reversible barocaloric effects in natural rubber cup lump and in technical specified rubber TSR-10, both at near room temperature and over a wide temperature range. Giant adiabatic temperature change and giant isothermal entropy change up to 14 K and 100 $J.kg^{-1}.K^{-1}$, respectively, were achieved for a maximum pressure change of 250 MPa. The results are comparable to the best barocaloric materials reported so far, encouraging new prospects for the application of more sustainable and renewable resources of solid refrigerants in the near future of solid-state cooling devices.

Glass nano-structuring with argon as etching gas

A major issue for the installation of photovoltaic modules is dust accumulation, known as soling, due to environmental conditions. This is a major problem in places where water is scarce, like desertic areas, which at the same time, have a enormous potential for photovoltaic energy due to its high solar irradiance. Thus, self-cleaning modules, with hydrophobic surfaces, come up as a solution for an efficient use of the available resources. Materials wettability properties can be modified by changing the micro or nanostructure of their surface [1]. For this purpose, a metallic film of few nanometers is deposited on the glass, then, through annealing, the film undergoes a dewetting process forming islands which will be used as masks during glass etching. Finally, the glass surface is modified through reactive ion etching (RIE) and the metallic film is washed out, obtaining a transparent glass with a nanostructured surface. Glass nanostructuring is commonly performed with gases like CHF3 or C4F8. However, C4F8 is an environmental hazard andCHF3 a particularly potent greenhouse gas, so their use should be avoided if possible. Inthis work, we nanostructured a glass surface through RIE by using only Argon as etchinggas and a gold nanomask. As a result, we grew amorphous nanostructures on the glass surface whose shapes and size depended on the initial thickness of the gold film, when keeping annealing temperature and RIE RF power as constant parameters. Using gold filmsof 5 nm and 20 nm resulted in nanostructures of 54±10 nm and 223±35 nm, respectively. Glass nanostructuring changed the wetting contact angle of the surface, from 35° (flat glass) to 50±5° and 67±5°, while optical transmittance decreased from 88% to 87%.

The development of chemical mechanisms towards storing energy has been increasingly a topic of notable relevance for our society. Redox batteries are interesting alternatives for storing electricity [1]. More specifically, zinc-iodine aqueous redox batteries (ZIRB) are interesting in several aspects, including low cost, high chemical stability, safety on handling and friendly environmental characteristics. On charging, $I^-$is oxidized and promotes the reduction of $Zn(OH)_4^{2-}$; the reverse process occurs during its discharge [2]. In this work, the $BiVO_4/V_2O_5$heterojunction was used as a photoanode to accompany the process of photoassisted battery charging. Under illumination, the stimulated photogenerated charges, at the electrode/electrolyte interface, promotes the oxidation of I^-, thus dropping the charge potential. The structural and morphological characterization of the synthesized materials in the laboratory were performed with different techniques, namely X-ray diffraction, transmission electron microscopy and scanning electron microscopy. The system efficiency was evaluated by voltammetry, chronopotentiometry and potentiostatic impedance. In order to simulate the sunlight spectrum, the photobattery was illuminated with an Xe light source. Charging the battery at a current density of 0.34 mA cm^{-2}, in dark conditions, required a potential of 2.43 V, whereas, under light, the potential for the same charge dropped by ~11.9%, reaching a specific load capacity of 500 mA h g^{-1}. The present results add to the technological development in the field of photoelectrochemistry to building water redox batteries, along with boosting further research and development on chemical storage of electricity generated from renewable energy sources.

e-mail: marianadebritoferraz@gmail.com

Hydrogen is a promising energy carrier [1]. Metal hydrides and multicomponent alloys are studied for hydrogen storage and designing materials with optimized properties. The Ti-V-Nb-Cr system has been extensively studied [2], but high-purity elements are often used. In this work, the (TiVNb)65Cr35 alloy was synthed by arc melting using scraps and commercially pure elements. Ti was added by using Ti-CP2 machining chips, commercially Nb from Brazilian Company of Metallurgy and Mining, and Cr from steel making industry were employed. Only high purity V was employed since no commercially pure V was available. Raw material and alloy were characterized by X-ray diffraction and scanning electron microscopy, and the hydrogen storage properties evaluated via SETARAM Sieverts-type apparatus. Differently from the same alloy produced from high purity elements that presented body centered cubic structure, the (TiVNb)65Cr35 produced here solidified with single C15-type phase structure (a = 7.045Å). The alloy was able to absorb 0.6 H/M withoutany activation treatment. Therefore, it was shown that the use of less pure alloying elementsfor alloy production can affect both structure and, consequently, hydrogen storage properties of alloys with same nominal composition.

"Multicomponent alloys" is a class of materials that can offer countless possibilities for new metal hydrides with tunable hydrogen storage (H_2S) properties. In these applications, the alloys are usually prepared by a simple mixture of five or more A and B elements (A: elements forming hydride, B: elements with low chemical affinity with hydrogen), in equiatomic or non-equiatomic fractions that range from 5 to 35 at% [1, 2]. In this study, we investigate the crystal structure and the hydrogen storage properties of two novel equiatomic multicomponent alloys: TiZrNbCrNiCo (AB-type alloy) and TiZrCrMnFeCo (AB_2-type alloy). These compositions were selected based on thermodynamic calculations that indicated a high tendency to form C14 laves phases, which is beneficial for storing hydrogen at room temperature. The alloys were obtained by arc melting under an inert argon atmosphere. Characterization techniques such as XRD with the Rietveld refinement method, SEM/EDS, and TEM were used to analyze the alloys' microstructures. The hydrogen storage performance will be evaluated using absorption/desorption kinetics and PCT isotherms. Preliminary results indicated that both alloys have a single C14-laves phase, in accordance with the thermodynamic calculations provided by the CALPHAD method. It is expected that both alloys show an interesting hydrogen storage capacity with good absorption/desorption kinetics. The H_2S results are expected to be distinct, due to the different fractions of A andB elements between the compositions.

e-mail: fantiqueira@uol.com.br

The hydrogen storage in solid state can be achieved safely and conveniently through various alternative materials. The Mg/MgH_2system is a strong candidate in solving hydrogen storage due to its high gravimetric (~7.66 wt.% H_2) and volumetric (~110 kg $H_2.m^{-3}$) capacities. However, the need for additives in Mg/MgH_2-based systems is necessary to accelerate the kinetics and reduce the H_2absorption/desorption temperatures. In a previous work [1], we evaluated the performance of Mg/MgH_2reactions with H_2, focusing on the effects of additives at temperatures below the equilibrium temperature of 283 ºC @ 1 atm, starting from room temperature. Traditional additives such as Nb_2O_5, Fe, TiFe, and TiAl evaluated in other studies at higher temperatures have shown to significantly affect the kinetics and conversion of Mg to MgH_2at lower temperatures. Among the tested additives, the best performance was observed by adding TiFe to Mg/MgH_2, which was attributed to the attraction of hydrogen to the high-energy interfaces between phases. Additionally, the TiFe intermetallic compound, composed of immiscible elements with Mg/MgH_2, proved to be stable during reactions with hydrogen. In this work, we review the results associated with the use of TiFe added to the Mg/MgH_2system based on the available literature and calculations of formation enthalpies at the interfaces between phases using the extended semi-empirical Miedema model [2]. Based on the possible role of interface energies, it is suggested that other Ti-based compounds may have a considerable effect on accelerating the kinetics and conversion of Mg to MgH_2, in addition to TiFe.

e-mail: joao.morais@unesp.br

Melanins have become promising materials for application in pseudocapacitive energy storage systems due to the relationship among the redox activities of their base monomer and the ability of different functionalizations to reversibly bind to cations [1]. In this work, we investigated how the concentration of carboxylic groups present in sulfonated melanins (SMel) affect the electrochemical performance of poly(3,4-ethylenedioxythiophene)-poly(styrene sulfonate) (PEDOT:PSS) as electrode in supercapacitors (SCs). The concentration of carboxylic groups of SMel was controlled by the synthesis process using temperature (SMel-T) or oxygen pressure (SMel-8P) for the monomers oxidation. The blend was deposited by drop casting on stainless steel and poly(vinyl alcohol)/phosphoric acid (PVA/H_3PO_4) gel electrolyte was used to assemble symmetrical solid-state SCs. Fourier transform infrared (FTIR) and X-ray excited photoelectron spectroscopy (XPS) results showed that the concentration of carboxylic groups increased for SMel-8P compared to the SMel, while decreasing for SMel-T. Cyclic voltammetry and galvanostatic charge/discharge results indicated an improvement in gravimetric capacitance after addition of melanins. We observed a dependence on the concentration of carboxylic groups, reaching values of 9.9 F $g^{-1}$and 0.8 Wh kg^{-1}after the SMel-8P addition. The best ion injection was attributed to the greater conductivity of the protons of the melanins with greater amounts of carboxylic groups, which helped in the doping of PEDOT:PSS, increasing its electrical conductivity. So, our results show that the addition of SMel leads to an improvement in the electrochemical properties of PEDOT:PSS and evidences the role of the carboxylic group in energy storage. The biocompatibility of the materials tested as electrodes allows their future application as wearable devices.

Among renewable energy sources, the fuel cells, as electrochemical devices that transform chemical energy of certain fuels to electrical energy by redox reactions, have been disseminated as an important alternative to be considered [1]. The solid oxide fuel cells (SOFC) with intermediate temperatures (500 - 800 °C) of operation gained attention for electrical energy production because of their capacity to be fed with reformed fuels (e. g. ethanol) [2]. In this work, a cathodic material, the strontium cobaltite ($SrCoO_{3-\delta}$), was synthesized by the methods of copreciptation, combustion with urea, Pechini and gelatin. The synthesized powders were calcined at 1.000 °C for 4 hours and characterized by X-Ray Diffraction (XRD) and Scanning Electron Microscopy (SEM). The synthesized powders were mechanically mixed with gadolinium-doped ceria ($Ce_{0.9}Gd_{0.1}O_{2-\delta}$- GDC) to produce the composite samples. The films were deposited on GDC substrates by the screen-printing method and, after, were sintered at 1.100 °C for 6 hours. Lastly, the cathodic films were characterized by Impedance Spectroscopy and SEM. With the chosen synthesis methods, it was verified their influence on microstructure and electrical characteristics. The synthesis method that produced the material with monophasic perovskite structure and lowest area specific resistance (ASR), of 0.0543 $\Omega\cdot cm^2$, was the Pechini method.

Investigation of ECAP prossessing on the microstructure of the Ti-29Nb-13Ta-4Nb alloy

Luigi Nogueira Mancuso[1], Sydney Ferreira Santos[1], Anibal de Andrade Mendes Filho[1], Alexandre N Ribeiro[1]

[1]Federal University of ABC

e-mail: mancuso.luigi@aluno.ufabc.edu.br

In the present work, we investigated the effect of Severe Plastic Deformation (SPD) process by Equal Channel Angular Pressing (ECAP) technique on the the Ti-29Nb-13Ta-4Nb alloy. As reported in the literature, the microstructure refinement by SPD can enhance the kinetics of hydrogen absorption and desorption in hydride-forming alloys for hydrogen storage [1]. The influence of the number of ECAP passes was analyzed up to 8 passes. Morphological and structural characterizations were carried out by confocal scanning laserMicroscopy (CSLM), scanning electron microscopy (SEM), and X-ray diffraction (XRD) to correlate the effects of processing parameters on the samples microstructures. The effect of ECAP in the samples was also assessed by nanoindentation tests. The morphological results obtained by SEM showed a reduction in grain as function of the number of ECAP passes. Nanohardness was increased as function of ECAP passes showing the higher value for 6 passes. Further characterization techniques were employed to fully understand the effect of ECAP on the microstructural evolution of the investigated alloy.

Ion intercalation kinetics in Prussian Blue electrodesand analogues

Alexandro Amorim Linhares[1], Felipe Backendorf[1], Renê Santos de Amorim[2], Deise Schafer[1], Cristiani Campos Plá Cid[1], André Avelino Pasa[3]

[1]Universidade Federal de Santa Catarina (*Física*) , [2]Universidade Federal de Santa Catarina (*Química*) , [3]Universidade Federal de Santa Catarina

e-mail: a.a.linhares10@gmail.com

The present work investigates the intercalation kinetics of potassium ions in Prussian Blue electrodes and analogs (PB and PBAs), materials that have potential application as cathodes of rechargeable batteries due to their high theoretical capacity, low production cost, chemical stability, crystalline structure (a = ~10 Å) and are eco-friendly [1]. PB is a semiconductor that exhibits a three-dimensional framework structure with interstitial water molecules that can be replaced by alkali cations during charging. However, the diffusion of these cations through the PB structure is hindered by its low intrinsic electronic conductivity and poor ion diffusion coefficient, leading to slow intercalation kinetics [2]. The main objective of the study is to use electrochemical techniques to determine the diffusion coefficient and to describe the kinetics of intercalation of potassium ions in PB electrodes and PBAs grown by electrodeposition. The techniques employed are electrochemical impedance spectroscopy (EIS) and intermittent potentiostatic titration (PITT) [3]. Based on the existing literature, diffusion coefficients can vary between 10-5 to 10-15 cm²/s across different techniques, systems, and assumptions [4]. However, in our case, we have obtained diffusion coefficients in the range of 10-10 cm²/s for Prussian Blue electrodeposited at 0.3 VSCE in a electrolyte containing 1M KCl.The samples were also characterized electron microscopy, X-ray diffraction, and optical measurements. This study will contribute to the elucidation of the mechanisms involved in the charge/discharge processes in Prussian Blue electrodes which can contribute to their use in sustainable batteries that employ abundant non-toxic elements and aqueous electrolytes.

Iron Hexacyanoferrate ($Fe_4[Fe(CN)_6]_3$), known as Prussian Blue (PB), is a material that presents physical properties that make it promising for application in battery electrodes [1]. PB is known for its chemical stability, non-toxicity, and low production cost. For having a crystalline structure with a lattice parameter around 10 Å, it easily accommodates ions in its crystalline interstice, an interesting strategy for applications in energy storage devices [2]. In this study, PB thin films were grown using the electrodeposition technique, and an electrochemical battery was simulated in order to study the impact of the insertion and extraction process of potassium ions (K^+) on the crystalline structure. Characterizations were performed on the samples before and after the battery tests: crystalline structure, morphology, chemical composition, and optical properties. The results reveal that the as-deposited films have a cubic morphology, face-centered cubic crystal structure (FCC) with a lattice parameter of 10.21 Å and preferential orientation [200], in addition to being a semiconductor with a direct gap. After the battery tests, a decrease in the lattice parameters of 0.79 % was observed by the insertion of ions, and a 1.89 % increase after the extraction of ions, without significant alteration in the crystalline structure, suggesting a process of intercalation of ions in the PB lattice. Characterizations made through Raman spectroscopy between the extraction and insertion tests indicate that the material is most stable under tests that end with the extraction process.

Thermochemical heat storage (THS) devices are consolidating as efficient solutions to energy problems [1]. In THS systems, the heat released (stored) is energy from the ruptureof chemical bonds in a reaction, i.e., endothermal heat. The storage features, as well as the storage density, correspond to the phase transition temperature of the PCM (phase-change material) [2]. In other words, a PCM material is a substance that absorbs and releases sufficient energy at phase transition to provide useful heat. In this work, the crystal Na2Mn(SO4)2(H2O)2 with a kröhnkite-type structure was explored for this purpose. The crystals were grown using the slow solvent evaporation method. The structural and thermal properties were investigated by X-ray diffraction (XRD), thermogravimetry (TG), differential thermal analysis (DTA), and differential exploratory calorimetry (DSC). XRD and Rietveld refinement analyses show that at room temperature, Na2Mn(SO4)2(H2O)2 crystallizes in a monoclinic system with space group P21/c. TG-DTA thermograms disclose thermal stability from 300 K to about 410 K, followed by structural changes due to transitions and phase transformations with increasing temperature. A dehydration latent heat of 169.38 kJ/mol was estimated from the DSC curve. The dehydration process takes place in 3 stages. XRD asa function of temperature (300-653 K), corroborates the transitions and phase transformations. Furthermore, a hygroscopicity test after thermal treatment at 583 K reveals partial rehydration after 24 h at ambient conditions. The results suggest that more studies should be carried out before assuming Na2Mn(SO4)2(H2O)2 as promising for applications in thermochemical energy storage devices.

Solid-state refrigeration, based on i - caloric effects has been considered an economically viable and environmentally friendly alternative to replace conventional vapor cooling systems. Several types of materials have been classified as promising for application on solid-state refrigeration subject to the mechanocaloric effect. One of these potential materials are polymers which present good performance on elastocaloric, barocaloric, or twistocaloric effects. The investigations regarding polymers showed some of the desirable properties suggested by Lloveras and Tamarit [1] for their use as solid-state refrigerants. For example, these polymers could present giant ∆TS and ∆ST within a wide range of temperatures, under low to moderate pressures, besides good reversibility, good availability, and low cost. Despite showing a giant and supergiant barocaloric effect, polymers are challenging to be employed in mechanocaloric cooling devices due to their limitations, such as low density, low thermal diffusivity, and low thermal conductivity. Due to these unique characteristics, we investigated the compressive mechanocaloric effect of Natural Graphite/Thermoplastic polyurethane (NG/TPU) composites. They are promising candidates for caloric cooling applications, as they combine similar rubber properties with the processability of thermoplastics. The NG/TPU composites presented ∆TS = 8.59 K and ∆ST = 35.01 J kg−1 K−1, which correspond to a maximum reduction of 28% and 45% in the∆TS and ∆ST, respectively, when compared to pure TPU, but with an increase of 500% inthermal conductivity. Our findings combine a large mechanocaloric effect with the unique characteristics of TPUs and the enhanced thermal conductivity of its NG composite.

Over the past decade, the high demand for nonrenewable fossil fuels in diverse branches of society has occasioned excessive CO2 emission into the atmosphere, which provides an environmental imbalance that becomes a cause for global warming. Aiming the CO2 emission to decrease and improve air quality in diverse cities, many resources for clean energy production, such as hydrogen, sunlight, and wind, can be considered. Among these, green hydrogen gas is the most promising and can be produced from electrochemical water splitting via hydrogen evolution reaction (HER). Thus, here, iron-based magnetic nanocrystals (FeM@OAm, M = Ag, Co, Cu, and Ni; OAm = oleylamine) electrocatalysts were synthed via the oleylamine reduction of metal salts method. FeCo is arranged in a body-centered cubic unit cell, while FeNi, FeAg, and FeCu are in a face-centered cubic structure. All the samples have different morphologies with an average diameter of 6.4 ± 1.0 to 21.7 ± 5.1 nm, depending on the bimetallic composition. The samples have ferrimagnetic behavior with a low coercive field and high saturation magnetization values at room temperature. Among heterogeneous electrocatalysts synthed, FeCo nanocrystals show lower overpotential (−564 mV) in comparison to FeAg (−584 mV), FeNi (−666 mV) and FeCu (−591 mV). The Tafel plots showed that the hydrogen evolution reaction (HER) activity for electrocatalyst following a mixed Volmer-Heyrovsky reaction mechanism suggests that reaction Volmer is the determining step. In addition, all electrocatalysts showed stability in tests of continuous operations showing only low potential variation. The EIS study shows a system characterized by two time constants, which may relate to the kinetics of the HER related to the charge transfer kinetics and the hydrogen adsorption. Thus, these materials showed acceptable electrocatalytic performance toward HER in alkaline media with excellent physical stability and an abundance of active sites for HER.

Malt bagasse hydrochar decorated with Co nanoparticles for hydrogen fuel generation

Marcela Mendes Ferreira[1], Iterlandes M. Júnior[2], Aline Aparecida dos Santos Silva[1], Renata Pereira Lopes Moreira[2], Tiago Almeida Silva[1]

Hydrogen (H_2) gas has been presented as a sustainable and very promising alternative fuel considering its high potential energy (1.42×10^8 J Kg^{-1}). However, its widespread use as a fuel is restricted by the safety and feasibility problems associated with the current storage systems. One way to get around this problem is to develop catalytic hydrogen generation technologies based on solid hydrogen storages, such as sodium borohydride ($NaBH_4$) [1]. In this work, the hydrogen generation performance of new nanocatalysts based on Ni and Co supported on hydrochar (HC) synthesized from malt bagasse was evaluated. The HC was synthesized by hydrothermal route (150ºC; 14 h) [2] using previously dried and ground malt bagasse. A broad characterization of the HC material was conducted (SEM, FT-IR, CNHS and TG/DTG), and it was possible to verify the production of a HC that preserved oxygenated functional groups. Ni and Co nanoparticles were supported on HTC using a reductive chemical synthesis method. The hydrogen evolution reactions were carried out using $NaBH_4$aqueous solutions in the presence of different catalyst compositions. Thus, the nanoparticles were synthesized with different Ni-Co proportions: 0%:100%, 20%:80%, 40%:60%, 50%:50%, 60%:40%, 20%:80%, 100%:0%. From this comparative study, it was observed that the use of monometallic Co nanoparticles supported on HC was the best catalyst. Then, the effect of adding NaOH to the medium was also studied, with a significant improvement in yield and reaction kinetics being verified. In the optimal condition (i.e., Co/HC catalyst at 0.5 mol L^{-1}NaOH), it was possible to obtain an average rate for H_2production at room temperature of 0.09 mL H_2s^{-1}(33 mL of H_2).

e-mail: johnnyshortencio@outlook.com

The electrochemical water splitting is one of the most promising and renewable methods to produce clean H_2, however some shortcomings still persist, especially for the oxygen evolution reaction (OER) [1]. Therefore, new methodologies to obtain high performance electrocatalysts based on Earth-abundant metals has gained attention. Thus, this work reports the obtention of a Mn-doped copper oxide composite, named $CuO/Cu_2O/Mn10$, through calcination of Metal-Organic Frameworks (MOFs), applied as electrocatalyst for OER. The material was characterized by XRD, vibrational spectroscopy (FT-IR and Raman), confirming the crystalline phases and chemical composition. SEM-EDS shows a rice-like morphology and indicates the presence of Mn homogeneously distributed in the sample. Electrocatalytic performance of $CuO/Cu_2O/Mn10$ was investigated by linear scanning voltammetry (LSV), cyclic voltammetry and electrochemical impedance spectroscopy, in alkaline KOH solution (1.0 mol/L). The material shows an excellent overpotential of 355 mV (at J = 10 mA cm^{-2}) and Tafel slope of 78.4 mV dec^{-1}. These results are similar or superior to other CuO and Cu_2O-based materials in the literature [2,3].

Acknowledgments: This work was supported by CNPq, CAPES and FAPESQ.

Microstructural characterization of SSZ-13 zeolites for membrane-based N2/CH4 gas separation

Daniel Dornellas Athayde[1], Daniel Augusto Alves Ladislau[2], Nelcy Della Santina Mohallem[2], Alysson Martins Almeida Silva[1]

e-mail: ddathayde@gmail.com

Zeolite membranes have presented promising capacity for gas separation [1]. For instance, the SSZ-13 zeolite displays a 3D structure with pores of 0.38 nm, allowing separation of gas molecules of similar kinetic diameters such as N2 (0.36 nm) and CH4 (0.38 nm) [2]. In this study, the hydrothermal synthesis with TMAdaOH (organic structuring-directing agent) was analyzed for SSZ-13 synthesis based on two different Si precursors, TEOS [3] and colloidal silica (Ludox AS-40) [1]. The duration of the hydrothermal synthesis was also analyzed within 1-4 days. Assessment of the zeolite microstructural properties was done by X-ray diffraction, microscopy (SEM), infrared spectroscopy (FTIR), gas sorption and thermogravimetry. All samples were crystalline, with exception to the sample obtained with Ludox using 1 day hydrothermal synthesis. SEM analysis revealed that the samples produced by TEOS presented cubic geometry (1-3 μm) whereas the samples obtained with Ludox formed larger (~50 μm) and multifaceted particles. SSZ-13 particles had high specific surface areas (>600 m2/g) with microporous structure (pore size 0.755 nm - typical of the 3D pores on the SSZ-13 structure with 0.38 nm pore windows). The thermal behavior of the samples revealed a 24% mass loss at 700 °C. Finally, preliminary trials on membrane production were performed by hydrothermal synthesis on top of alpha-alumina tubes (both commercial and freeze-cast tubes). The influence of the Si precursor on the SSZ-13 structure and the duration of the hydrothermal synthesis allowed precise control of the SSZ-13 properties, revealing the most adequate conditions for membrane manufacture.

Zeolite LTL has 12-membered-ring one-dimensional (1D) channels with an accessible diameter of 7.1 Å, which turns the intracrystalline diffusion resistance lower than those of small-pore zeolites. Due to its crystal anisotropy, zeolite LTL has attracted attention for applications such as heterogeneously catalyzed hydrogen production [1] and gas separation [2]. The conventional synthesis of zeolite LTL is under hydrothermal conditions using high-pressure vessels and heating with ovens. This work describes a conventional and microwave synthesis of zeolite LTL (K, Sr) and its characterization. The synthesis was performed with a gel composition of $2.3K2O$: $0.2SrO$: $Al2O3$: $9SiO2$: $160H2O$ at 150 °C [3]. XRD patterns showed that the sample prepared by conventional synthesis for 1 day was composed mostly of amorphous phase. Otherwise, sample prepared for 3 days displayed very sharp diffraction peaks assigned to the characteristic planes of zeolite LTL. The results of microwave synthesis indicated that 12 h was enough to produce crystalline zeolite LTL (K, Sr). FTIR spectra confirmed the zeolite structure with bands in frequencies characteristic of this material. Moreover, zeolite LTL (K, Sr) exhibited a cylinder morphology in SEM images. BET specific surface area (184.28 m2/g) and total pore volume (0.111 cm3/g) of zeolite from conventional synthesis are lower than those of microwave-synthesized sample (238.29 m2/g and 0.139 cm3/g). Therefore, microwave heating is a simple and effective technology that reduces the synthesis time of zeolite LTL (K, Sr).

e-mail: caroline.claudino@aluno.ufabc.edu.br

As with any material, the synthesis conditions affect the characteristics of the resulting system. Traditionally, (g-C3N4) is synthesized through the pyrolysis of urea [1] or melamine [2]. On the other hand, only a few papers discuss the hydrothermal treatment of the precursor before the calcination step [3]. The use of microwave-assisted techniques in synthesizing this material is not known to us. In this context, we developed a microwave-assisted hydrothermal synthesis route of (g-C3N4). The properties of the resulting material were compared with those observed for materials prepared by conventional routes, aiming to evaluate the existence of thermal and non-thermal effects. Our results show that using microwaves reduces the reaction time from 24h (under conventional heating) to 2h40 (under microwave heating). As a result, materials with similar morphologies, crystalline structures and photoelectrochemical responses are obtained. This result may be ascribed to the thermal effects of microwaves, which increase the heating rates.

Poly(3,4-ethylenedioxythiophene):polystyrene sulfonate, PEDOT:PSS, is a well-known polymer blend used in organic electronics due to its electrical conductivity, flexibility, and optical transparency. It is known that mixing this compound with Graphene Oxide (GO) in a defined proportion can decrease the electrical resistivity of the samples up to three orders of magnitude to be applied as transparent electrodes in organic photovoltaic devices [1]. This study presents a theoretical model using the Kirchhoff’ s Circuit approach for these systems to elucidate the reasons for having a minimum corresponding to 5% of PEDOT:PSS into GO aqueous dispersion. This Modified Nodal Analysis methodology simplifies the evaluation by using a square lattice representation [2]. After calculating the equivalent resistivity of the system, it reveals a minimum spot that fits well with the experimental data mentioned before. There are also studies showing that GO can enhance the sensitivity of flexible gas sensor devices for methanol detection using PEDOT:PSS as active layer, with a well-defined maximum spot [3]. The model was further applied to these systems, revealing the same agreement between theory and experimental data.

Electrochemical capacitors (supercapacitors) play a key role in the development of new technologies for energy storage applications [1]. This work aimed to investigate nanoparticles of pure copper oxide (CuO) and the addition of different proportions of zinc oxide (CuO/ZnO) in relation to possible properties suitable for electrodes for electrochemical capacitors. The nanostructures were synthed by combustion reaction, the first sample consisting of 100% CuO and the second 80% CuO with the addition of 20% ZnO as initial test parameters. The samples were characterized by X-ray diffraction (XRD), infrared spectroscopy (FTIR), thermogravimetric analysis (TGA). The results of the structural and thermal characterizations revealed the formation of the desired crystalline phases, with all well-defined diffraction peaks and high organization at long range, in addition to good thermal stability with a total mass loss of only 7%. The electrochemical performance of the synthed nanoparticles, from an electrode prepared for supercapacitor, was studied by means of cyclic voltammetry, electrochemical impedance spectroscopy, and constant current charge and discharge method, from which relevant results were obtained, indicating that the samples of the metallic oxides studied have promising properties for the desired application.

Solid-state cooling based on the *i*-caloric effect is being explored as a potential replacement for conventional vapor-compression refrigeration systems. Although recent research has shown that elastomers have potential as barocaloric materials for cooling applications nearroom temperature, their insulating nature presents a disadvantage that can compromise practical use, since higher heat transfer properties are typically desired for increased efficiency. To address this issue, we investigated the barocaloric effect in composites consisting of natural graphite and polydimethylsiloxane (PDMS) at different mass proportions. Our findings are promising for solid-state cooling based on barocaloriceffect, as the composites exhibit a combination of desirable properties. When natural graphite was added to PDMS, the adiabatic temperature change (ΔT_S) and isothermal entropy change (ΔS_T) of the resulting composites decreased in comparison to pure PDMS. For example, at 323 K for 390 MPa of pressure change, pure PDMS demonstrated ΔT_S = 30.6 K and ΔS_T = −130 J.kg^{-1}.K^{-1}, while PDMS with 40 wt.% of natural graphite showed ΔT_S = 20.2 K and ΔS_T = −68 J.kg^{-1}.K^{-1}. However, the thermal diffusivity of the composites increased from 1.18×10^{-7} to 7.3×10^{-7} m^2.s^{-1}, an equivalent increase of ~500%. The natural graphite/PDMS composites were found to be superior or comparable to other barocaloric materials in the literature in various developed figures of merit.

New mixed Tutton salts with composition $K_2Mn_{1-x}M^{II}(SO_4)_2(H_2O)_6$, M^{II}= Co^{2+}, Ni^{2+}, Cu^{2+}, and Zn^{2+} for use in thermochemical and optoelectronic devices

Hydrated double salts have gained much notoriety in materials science and engineering, due to the structural, thermal, and optical properties that these crystals present, which are of commercial interest for the development of thermochemical energy storage systems and fluorescent devices [1, 2]. With this in mind, a mixed Tutton salts series were synthesized with composition $K_2Mn_{1-x}M^{II}(SO_4)_2(H_2O)_6$, M^{II}= Co^{2+}, Ni^{2+}, Cu^{2+}, and $Zn^{2+}$by the isothermal evaporation method after 14 days. The properties were characterized by X-ray diffraction (XRD), thermogravimetry (TG), differential thermal analysis (DTA), differential scanning calorimetry (DSC), and spectroscopic techniques. In addition, a computational study was conducted through Hirshfeld surfaces and crystal voids to identify intermolecular interactions and lattice-free spaces. The XRD results confirmed the unprecedented nature of the double salts, in which all samples crystallized in a monoclinic system (*$P2_1/c$*). In addition, the thermal analysis revealed that the crystals have thermal stability ranging from 76 to 96 °C. Complementarily, the values calculated from the DSC thermograms showed that all 4 Tutton salts synthesized here, present enthalpy values and energy density promising for use in thermochemical systems. Moreover, the spectroscopic data in the emission regime showed that all salts exhibit photoluminescence in the visible region, which makes these materials interesting for application in solid-state lighting. Besides, it is worth mentioning the low cost and efficiency in the analyzed physical properties of these single crystals.

e-mail: mengyingma@id.uff.br

We proposed to use carbon cloth (CC) as a support for nickel nanoparticles (NiNP/CC) prepared by Pulsed Laser Deposition (PLD) at three different deposition times (20 s, 40 s, and 60 s) as catalysts for urea electro-oxidation reaction (UER) in alkaline media. Scanning Electron Microscopy (SEM) and Energy Dispersive X-Ray Spectroscopy (EDS) were used to characterize the materials. The SEM analysis shows that they were deposited uniformly onto the CC surface and gradually agglomerated with the increase of deposition time. The electrochemical characterization by cyclic voltammetry (CV) in 1 mol L^{-1} KOH showed that the characteristics peaks of $Ni^{2+}[Ni(OH)_2]$ oxidation and Ni^{3+}(NiOOH) reduction were present in all three synthesized samples. Electrochemical Impedance Spectroscopy (EIS) depicted a less resistive material as the nickel deposition time increased. Regarding UER, the maximum current density from CV experiments (normalized by geometric surface area of the electrode - GSA) in NiNP/CC 60s catalyst was approximately 15% higher than that in NiNP/CC 40s and about 49% higher than that in NiNP/CC 20s. However, the results related to UER from CV experiments normalized by electroactive surface areas (ESA) showed the maximum current density obtained with NiNP/CC 20s catalysts was around 35.5% and 67.9% higher than that obtained with NiNP/CC 40s and NiNP/CC 60s catalysts, respectively. Chronoamperometry (CA) measurements demonstrated that all the three materials had suitable electrocatalytic stability towards UER after 30 min of experiment. The highest current density of CA was obtained using NiNP/CC 60s when normalized by GSA. However, NiNP/CC 20s was responsible to the highest current density from UER at the end of the experiment when normalized by ESA. EIS measurements proved that the charge transfer resistance significantly decreased for UER as the electrocatalytic activity of nickel nanoparticles increased.

Ni-Co bimetallic nanoparticles supported on Zn-C battery residual electrolytic paste as a sustainable catalyst for hydrogen evolution from NaBH$_4$

Renata Pereira Lopes Moreira[1], Iterlandes M. Júnior[1], Gabriel Henrique Sperandio[1] [1]Fundação

Universidade Federal de Viçosa (*Química*)

e-mail: renata.plopes@ufv.br

Hydrogen has a high energy potential (1.42x108 J Kg^{-1}), being considered the future fuel. However, its storage process such as gas compression or liquefaction are still unfeasible due to its low density and boiling point [1]. Thus, hydrogen storage in solid state, such as NaBH$_4$, are considered promising alternatives. The release of H2 from these compounds must be catalyzed. Catalysts from e-waste consists in a sustainable alternative for recovering and adding value to these materials [2]. In this work, the electrolyte paste (EP) from used cells was used as support of nanocatalyst for H$_2$ evolution. Firstly, the material was dried, crushed, and sifted (< 150 mesh). The recovered material presented diffraction peaks that correspond to the patterns of ZnMn$_2$ O$_4$ (hetaerolite), graphite and Zn$_5$(OH)8Cl$_2$·H$_2$O (simonkolleite). By FTIR, bands were observed that were attributed to MO bonds M and MO (M = Zn, Mn), Co-O and Ni-OH. By Raman spectroscopy, characteristic graphite bands were observed at 1354, 1580 and 2697 cm^{-1}. Bimetallic nanoparticles of cobalt and nickel (2:8), Ni-Co NPs, were supported on this material by chemical reduction with NaBH4, with bands corresponding to the vibrational mode of Ni-O being observed at 518 cm^{-1} and of Co$_3$O$_4$ at 470, 512, 604 and 667 cm^{-1}. By High Resolution Transmission Electron Microscopy (HRTEM), graphite-like sheets with an interplanar distance of 0.34 nm were confirmed. The nanoparticles had a of 1.35 + 0.67 nm. The catalyst showed a good performance in the evolution of hydrogen through the alkaline hydrolysis of NaBH4, at room temperature, with efficiency close to 90% in the first reaction cycle with activation energy of 41.1 kJ mo^{l-1}. The Ni-Co NPs (2:8)/EP material showed significant efficiency for up to 16 catalytic reuse cycles and 11 catalytic cycles of durability and turnover frequency (TOF) from 315.9 mL H2 g catal^{-1} min^{-1}.

One-pot conversion of lignocellulosic biomass-derived compounds using hierarchical ZSM-5 zeolites as catalysts

Sancler da Costa Vasconcelos[1], Vinicius Rossa[1], Domingos Sérgio Araújo Silva[2], Monize Picinini[2], Ernesto A. Urquieta-González[2], André Von-Held Soares[3], Fabio Barboza Passos[4], Thiago de Melo Lima[1]

e-mail: sanclervasconcelos@id.uff.br

The use of lignocellulosic biomass as a renewable feedstock has been proposed as an alternative to decreasing the dependence on fossil fuels. Platform molecules such as 5-hydroxymethylfurfural (HMF) and furfural can be used to obtain several value-added products with applications as biofuels and biofuel additives through hydrogenation reactions [1]. Such reactions can be performed using a one-pot approach, assisted by a catalyst containing Lewis and Brønsted acid sites and secondary alcohol as a hydrogen source. Zeolite-based catalysts are widely used in the industry, but their usage in biomass valorization reactions is hindered due to diffusional limitations. Therefore, chemical treatments can be performed to form hierarchical zeolites, containing both micropores and mesopores, to increase the efficiency in the conversion of the reagents and the catalyst lifetime [2]. In that context, this work aims to evaluate the viability of using ZSM-5 hierarchical zeolites with different Si/Al ratios (23, 38, 48, 50) formed through top-down methods and its usage in valorization reactions for the production of alkyl levulinates using domino-reactions. A desilication treatment was performed, and the effects on the structure and acidity of the zeolites were accessed through XRD, XRF, FTIR-Py, and TPD-NH3. Catalytic studies and design of experiments (DOE) were also carried out. As a result, the alkali-treated Z23 zeolite presented the highest FUR conversion and selectivity to isopropyl levulinate (98 and 95%, respectively).

e-mail: fccolman@uem.br

Replacement of vapor cooling systems with less impactful technologies is one of the many forms to address climate change. Solid-state refrigeration is one of the promising solutions as it virtually eliminates the use of greenhouse gases by replacing them with solid refrigerants. Concerning barocaloric technology, the research focuses on discovering barocaloric materials that can be applied as solid-state refrigerants. One of these potential barocaloric materials are polymers that present giant values of ΔT_S and ΔS_T within a wide temperature range for elastomers like natural rubber (NR)[1], acetoxy silicone rubber (ASR) [2], and commercial thermoplastic elastomers [3]. Despite the expressive number of works reporting the giant barocaloric effects. To date, no results of fatigue analysis have been reported in the literature considering materials with a compressive mechanocaloric effect (CME). In this work, we report the influence of the number of mechanocaloric cycles in the ΔT_S for the TPU and Natural Graphite/Thermoplastic polyurethane (NG/TPU) composites. The TPU and the composites with 20 and 40 wt% of NG/TPU were subjected to a rigorous fatigue test by cyclic compressive stress at 130 MPa (0.3 s^{-1}) in an experimental apparatus developed by the research grou at the end of the application of 10^5 cycles of confined compressive stress, no deterioration of the mechanocaloric compressive effect was observed.

Oscillating magnetic effect in $BiFeO_3$ samples: apossible application in batteries.

Thiago Ferro de Oliveira[1], Adrielson de Araújo Dias[1], José Holanda da Silva Júnior[1]

[1]Universidade Federal Rural de Pernambuco

e-mail: thiago.ferro@ufrpe.br

The development of electric cars led to the search for increasingly efficient batteries that bring less damage to the environment. In this context, it is evident that the study of new materials and effects to increase this efficiency is of fundamental importance. One of the materials that has characteristics that contribute to improving the quality of batteries is bismuth ferrite ($BiFeO_3$, or BFO), which is a perovskite that has been widely studied because it has characteristics suitable for various applications [1,2]. For example, its spontaneous magnetization can be controlled by a magnetic or electric field. Thus, in this work we carried out a detailed study of this ferrite using oscillating magnetic fields and observed that the BFO is sensitive to the frequency and shape of the magnetic fields. In fact, we observed a new effect through the transmission of electromagnetic signals on the perovskitesurface. The modulated magnetic ordering is important for the production of field sensorsbased on the oscillating magnetic effect, because when in the presence of magnetoelectriccoupling it is possible to detect magnetic fields through electrical output signals, which is important to evaluate the state and efficiency of the battery.

Palladium nanoparticles immobilized on graphene derivatives for hydrogen production via catalytic dehydrogenation of formic acid

Lucas Rodrigues de Oliveira[1], Natalia Łukasik[2], Joanna Elzbieta Kulesza[1], Bráulio Silva Barros[3]

[1]Universidade Federal de Pernambuco (*Departamento de Química Fundamental*) , [2]Gdansk University of Technology / Politechnika Gdanska (*Department of Chemistry and Technology of Functional Materials, Faculty of Chemistry*) , [3]Universidade Federal de Pernambuco (*Engenharia Mecânica*)

e-mail: lucas.roliveira@ufpe.br

Our group conducted a study in which palladium (Pd) nanoparticles (NPs) were immobilized on Reduced graphene oxide (RGO) functionalized with amine groups (Pd/RGO-NH2) using a simple wet reduction method. The presence of NH2 groups on the GO surface allowed the production of highly dispersed NPs with reduced s. This system exhibited exceptional catalytic performance for the mild decomposition of formic acid (FA), demonstrating total selectivity for the dehydrogenation route and complete suppression of carbon monoxide (CO) formation. In fact, we produced 78 mL of gas at 45°C in just 60 minutes, with an apparent activation energy value of 19.93 Kj.mol-1 and a hydrogen production rate equivalent to 65 mL.H2.min-1.g-1, which is comparable to the most effective heterogeneous Pd catalysts in the literature [1, 2, 3]. According to Han et al. (2021), the remarkable catalytic kinetics of our system may be attributed to the and high dispersion of the NPs on the support, as well as the contribution of the NH2 groups in the deprotonation of FA and the rapid formation of the formate ion (HCOO-). Moreover, recycling tests indicated that the catalytic activity remained stable until the fourth reaction cycle.

Photoanodes based on titanium dioxide and graphene oxide for application in hydrogen production

Jéssica Caroline Pena Alves da Silva[1], Juliana dos Santos de Souza[2] [1]Universidade Federal do ABC, [2]Universidade Federal do ABC (*Centro de Ciências Naturais e Humanas*)

e-mail: jessicapena.alves@gmail.com

Photoelectrochemical water splitting into H_2 and O_2 using semiconductors materials as photoelectrodes is a promising approach for obtaining hydrogen gas (H_2) [1]. TiO_2-based photoanodes have been widely investigated for this application due to their natural abundance, chemical stability, non-toxicity, high resistance to photocorrosion and low production cost. However, TiO_2 presents limitations such as low electrical conductivity, limited time in the excited state, and small diffusion distance. Incorporating graphene into TiO_2 increases the photoelectrochemical activity of the resulting material, attributed to the favorable band alignment of the two semiconductors and the properties of graphene that facilitate charge separation [2].

Here we report how the unique interactions of microwaves with the reactional media can produce TiO_2-graphene composites with enhanced properties. The method of synthesis used was adapted from previously reported conventional synthesis [2], with adaptations for microwave conditions. Also, ammonium sulfate was added as a capping agent to orientate the TiO_2 growth. Raman data show that it was possible to form anatase TiO_2 under all the synthesis conditions investigated. Additionally, it was possible to evaluate the degree of graphene reduction, given that reduced graphene oxide is more conductive. Adding ammonium sulfate to the reaction medium also increases the degree of graphene oxide reduction when the reaction is microwave-assisted but has no impact on conventional synthesis. These differences show that the unique effects of microwave irradiation allow one to obtain materials with characteristics distinct from those observed in materials produced by traditional routes.

Photocatalytic fuel cells: fundamental concepts and applications

Heberton Wender[1]

[1]Universidade Federal de Mato Grosso do Sul (*Instituto de Física*)

e-mail: heberton.wender@ufms.br

The energy and environmental pollution crisis has become a recent worldwide concern. Photocatalytic fuel cells (PFC's) are energy converter devices that harvest solar energy using low-cost semiconductor electrodes to spontaneously convert the chemical energy of renewable fuels (or pollutants) and oxidants directly into electricity [1]. PFC's integrate photoelectrochemical and fuel cell technologies, having double benefits, i.e., to address environmental and energy problems. Since it has a simple engineering concept and uses only light as a driving force, low-cost PFC devices can be easily built to solve local environmental pollution or low-power energy-consuming problems [2]. This work presents essential definitions, working principles, and theoretical fundaments, including a hands-on tutorial on building devices and testing half-cell reactions and PFC's performance. In addition, some recent application cases will be presented and discussed in detail, focusing on critically debating strategies for boosting PFC's efficiency and stability.

e-mail: lucastienne@ima.ufrj.br

Poly(3-hexylthiophene), known as P3HT, is a semiconductor homopolymer that is considered a reference material for research in the field of organic photovoltaic devices (OPV)[1]. The PC61BM is his standard electron acceptor. Graphene is a very famous carbon allotrope, mainly due to its excellent set of properties, such as excellent electrical conductivity, transparency, flexibility and mechanical residence. Current methods of obtaining graphene are still not efficient enough to produce material on a large scale while still presenting good quality and properties. Graphene has also been applied in the field of photovoltaic devices. However, there is a difficulty in standardizing and controlling the quality of the materials obtained, which makes it difficult to compare the results among those surveyed around the world and, finally, compromising the understanding of the impact of this nanomaterial on photovoltaic devices. The present work synthesized P3HT by the GRIM route, graphene oxide(GO) and reduced graphene oxide(rGO) by the Hummers method improved by the research group. Then, a ternary mixture of P3HT:PC61BM (1:1) with different levels of GO or rGO added (0.5%; 1.0%; 2.5% and 5.0%) were prepared. Then, solar devices were manufactured using these materials as an active layer and the main photovoltaic parameters and morphology were evaluated. The GO, although it has lower electrical conductivity than rGO, improved the energy conversion efficiency from 2.6±0.3% to 2.8±0.1% mainly becauseit has oxygenated groups that add better affinity with P3HT, reducing exciton recombination. Both GO and rGO favor a higher Jsc due to the light trapping phenomenon. Preliminary studies also suggest that the insertion of graphene tends to preserve the efficiency of the devices for longer periods of time.

[1]Universidade Estadual de Ponta Grossa (*Departamento de Física*) , [2]Universidade Estadual de Ponta Grossa (*Departamento de Física*) , [3]Universidade Estadual de Ponta Grossa (*FISICA*)

e-mail: g.teixeira3399@gmail.com

Tellurite glasses have risen scientific and technologic interest for having wide optical transmission window (350-5000 nm), good vitreous stability (ΔT >100 °C), low phonon energy (600-850 cm^{-1}) when compared to basic silicate glasses $SiO_2$and high linear refractive index value (n ~ 2). The chosen system 65TeO2-15Li2O-20ZnO presented excellent results with promising properties in photonic application. Our work consists in the structural proprieties characterization of telluride glasses doped with $Nd_2O_3$for possible application in photonics. The samples were prepared using melting quenching technique, in ambient atmosphere. The obtained samples were characterized by the X-ray diffraction (XRD), a Raman spectroscopy technique, a Fourier transform infrared (FTIR) and using the density by Archimedes principle. The XRD analysis showed amorphous pattern without any spikes, which is typical for a vitreous sample. The Raman and FTIR techniques provided the information of a decrease in vibrational modes related to TeO_{3+1}unit. All other modes remain unchanged. These results means that the insertion of Nd_2O_3in composition does not alter the structural properties, meaning that we can consider this oxide as a dopant and not a network modifier. From density determination we observed that the oxygen packing density (OPD) increases up to 0,35% and then remains constant, this behavior complements the density results showing that the dopant increase the system density. The density increase is expected since we are adding a more dense material to the system.

Reverse Water Gas Shift Using Modified Titanate Nanotubes as Catalyst

Jéssica Pereira Pires[1], Wesley Formentin Monteiro[1], Marcus Seferin[1], Rosane Ligabue[1]

[1]Pontifícia Universidade Católica do Rio Grande do Sul

e-mail: jessica.pires.001@acad.pucrs.br

The search for ways to apply the Carbon Capture, Utilization, and Storage (CCUS) as strategy to CO_2mitigation has received relevant attention in the literature [1]. As $CO_2$is a thermodynamically stable molecule, their conversion in valuable chemical products is difficult. In this context, the reverse water gas shift (RWGS) can be used as an essential stage to the transformation of CO_2, which contribute to the mitigation of this gas. However, RWGS presents a bigger challenge that is the design of new catalyst that are capable to promote this conversion [2]. Titanate Nanotubes (TNT) modified with metals has been showing as a promisor catalyst to the CO_2conversion, presented high values of conversion and selectivity [3] and can be a good candidate to RWGS. In this context, the present work aimed to evaluate the efficiency of TNT modified with cooper (Cu), cobalt (Co), nickel (Ni) and iron (Fe) in the RWGS. From the better catalyst, the gas hourly space velocity (GHSV) was also evaluated. The results showed that Cu-TNT was the best catalyst, showing around 34% of CO_2conversion at 500 °C. In relation to the GHSV, the better result was obtained with 15000 $mL.h^{-1}g^{-1}$. Finally, a stability test was realized using the Cu-TNT and better GHSV. The result showed that catalyst was stable in 12 h of reaction leading the decrease less than 8% of CO_2conversion. These initial results indicate that Cu-TNT showed a promisor catalyst to RWGS reaction.

e-mail: yarajaque@hotmail.com

The alarming environmental problems are strongly related to the constant greenhouse gas emission, by the consumption of fossil fuel, as a mean energy source. This scenario highlights the necessity for new renewable and environmentally friendly energy sources, like green Hydrogen produced by water splitting, using sunlight and semiconductor photocatalysts [1]. A suitable candidate for this task is SrTiO3, due to its high photochemical stability in an aqueous environment and suitable energy band potentials for oxidation and reduction of the water molecule [1]. Despite its excellent characteristics, this semiconductor presents some drawbacks, like high recombination of photogenerated charges (electrons and holes) that demand modifications like the use of dopants and cocatalysts, to achieve high photocatalytic performance. In this work, was synthesized nanoparticulated molybdenum doped SrTiO3 by the molten salt method [2], and Rh2O3/CrxO3¬ cocatalyst was deposited into its surfacer by impregnation method. The physical properties of the photocatalyst were investigated by XRD, XPS, SEM, and PL. The photocatalytic activity of Mo:SrTiO3 was remarkably improved more than 700-fold for H2 evolution, after the deposition of Rh2O3/CrxO3¬. This behavior was attributed to the formation of a p - n junction of Mo:SrTiO3 (n-type) and the Rh2O3/CrxO3¬ (n-type), leadingto a high charge separation. The charge separation due to the p - n junction, was experimentally confirmed by photoluminescence measurements. This work highlights the excellent properties of Mo:SrTiO3/Rh2O3/CrxO3¬ as a photocatalyst for green H2 production through water splitting reaction.

Simulation of the Optical Properties of Multilayer Films Composed of Ag and ITO as an Artifice to Increase Electrical Efficiency in Crystalline Silicon Photovoltaic Cells

Lucas Medeiros de França[1], José Felix da Silva Neto[1], Kelly Cristiane Gomes[1], Marçal Rosas Florentino Lima Filho[1]

[1]Federal University of Paraíba (*Department of Renewable Energy Engineering*)

e-mail: lucas.franca@cear.ufpb.br

Due to climate change, several measures to mitigate carbon dioxide emissions have been adopted, one of which is the use of clean and renewable energy sources to decarbonize the world's energy matrix. In Brazil, especially in the Northeast region, there are high rates of solar radiation throughout the year, therefore, the use of solar energy to generate electricity becomes viable and contributes to global goals. Although photovoltaic cell technology has developed a lot in recent years, there are still problems to be solved, such as the influence of cell operating temperature on electrical performance, which is inversely proportional. Thus, this work aims to propose, through mathematical simulation, an optical filter of solar radiation composed of silver (Ag) and indium tin oxide (ITO). Several multilayer configurations were analyzed and their optical properties simulated in order to obtain a filter with high transmissivity in the region of the solar spectrum in which the photoelectric effect occurs for generating electricity in crystalline silicon photovoltaic cells, as well as high reflectivity in the region of solar spectrum with few relevance for energy generation and that contributes positively to their heating, impairing electrical efficiency. Through the simulations, some configurations were compared, with different amounts of layers and thicknesses, highlighting one of 5 alternating layers of ITO and Ag with 85% of average spectral transmissivity from 400 nm to 900 nm and 80% of average spectral reflectivity of 1100 nm to 2500 nm, pointing out that the filter with the proposed materials has promising optical properties for spectral beam splitting applications in order to increase the electrical performance of photovoltaic cells exposed to high rates of solar radiation.

[1]Universidade Estadual Paulista (*Departamento de Física e Química*) , [2]São Paulo State University, [3]São Paulo State University (*Física e Química*)

e-mail: denis.feis@gmail.com

The search for new methods of energy accumulation and storage is an important topic of research today [1]. In this regard, supercapacitors (SCs) are emerging as an alternative to conventional devices due to their performance and inherent advantages. Conductive polymer hydrogels (CPHs) are a new class of polymeric materials that combine the benefits of organic conductors and hydrogels. They exhibit remarkable synergistic properties aiming the expansion behavior and flexibility of hydrogels with the electroactivity of conductive polymers [2]. CPHs are also being used in the development of new energy storage devices, fuel cells, humidity-sensitive capacitors, photosensitive cells, and new SCs. The objective of this work was to perform spectroscopic and morphological analyses of CPHs composed of PAAm/CMC/PAni. It has been shown that CPHs, obtained from free radical polymerization [3] followed by interfacial polymerization using ammonium persulfate as an initiator, demonstrated good reproducibility and conductivity values on the order of 10-2 S/cm. The spectroscopic characterization showed characteristic bands of doped PAni, confirming its incorporation into the composites. The bands referring to polarons showed greater intensity, justifying the high conductivity of these composites. The morphological analyses showed PAni agglomerates filling the pores in the matrix, mainly closer to the surface of the hydrogels. The results also confirmed the formation of dendritic microcrystals attributed to the fractal growth of PAni. Finally, we can highlight that the composites presented good stability, reproducibility, and electrical performance, indicating their potential application as SCs.

SPINEL FERRITE MFe_2O_4 (M= Co, Ni, Zn) NANOPARTICLES OBTAINED BY HYDROTHERMAL ROUTE FOR OXYGEN EVOLUTION REACTION

Nayuca Alberto Bampoky[1], Igor Frota Vasconcelos[2], Luis Paulo Mourão dos Santos

[1]universidade federal do ceará (*departamento de metalurgia*) , [2]universidade federal do ceará*e-mail: nayucaalberto@hotmail.com*

Transition metal oxides have gained prominence due to their optical, magnetic, and electrolytic properties. In this work, MFe_2O_4(M = Co, Ni, Zn) ferrite nanoparticles (NPs) with spinel structure were synthesized, characterized, and successfully employed for water splitting as electrocatalysts for both the hydrogen and oxygen evolution reactions (HER and OER). The NPs were synthesized by the hydrothermal method. Stoichiometrically calculated amounts of metal sources were dissolved in distilled water and transferred to a Teflon vial under stirring. After stirring, the vial containing the homogenized solution was placed in an autoclave, sealed, and heated at 180° C for 3 hours. All samples were washed three times with water and alcohol and dried at 80°C for 12 hours. The X-ray diffraction (XRD) pattern showed characteristic peaks which confirmed the NPs spinel ferrite crystal structure. Absorption bands were observed within the 560-450 cm^{-1}range of the infrared spectra, corresponding to vibrations of M-O bonds at tetrahedral sites and Fe-O bonds at octahedral sites. Furthermore, the optical behavior of the NPs showed a single absorption band in the visible region of the electromagnetic spectrum. While all NPs showed considerable HER and OER electroactivity, $CoFe_2O_4$presented the best performance for both reactions.

Structural properties of Cr_2O_3-doped tellurite glasses

Giovanny Luttierri[1], Jaqueline Valeski Gunha[2], Andressa Novatski[3], Guilherme Teixeira Santos[2]

[1]Universidade Estadual de Ponta Grossa (*Departamento de Física*) , [2]Universidade Estadual de Ponta Grossa (*Física*) , [3]Universidade Estadual de Ponta Grossa (*FISICA*)

e-mail: giovannyviana580@gmail.com

Tellurite glasses have attracted particular attention due to their properties, such as high thermal stability (~ΔT = 100 ℃) [1], low melting temperature (~700 ℃) [2], wide transmission range (~0.35 - 5 μm), low phonon energy compared to silicate glasses (~600 -850 cm-1), high linear refractive index value (~2) and high solubility for rare earth ions. These properties make this family of glasses a good candidate for optical and electronic devices. An excellent application that demonstrates the efficiency of optical glasses in photonics is the use of optical fibres, which are becoming an increasingly important part ofpeople's lives. The transition metals are widely used to modify glass structures due to itshigh radial distribution, by consequence, generating extremely sensitive responses to changes in interactions, [3] transition metals influence the behaviour of the optical properties by generating absorption bands in the near infrared region, inducing excited state absorption. Among the many transition metals, we highlight the chromium (Cr_2O_3) when used in high doping concentrations, it influences in the optical structural properties ofthe glasses. In this work, we characterise the system TeO_2-Li_2O-ZnO doped with different concentrations of Cr_2O_3: 0.1; 0.25; 0.50; 1.0, and 2.0 in mol%. The samples were prepared by the melting quenching technique. The structural properties were obtained using X-ray diffraction (XRD), Raman spectroscopy, Fourier transform infrared (FTIR) and density by Archimedes method techniques. The XRD technique was used to verify the amorphous stateof the synthetic materials. By Raman and FTIR techniques we observed that there is anincrease in TeO_3 modes as the Cr_2O_3 content increases. This behaviour indicates that Cr_2O_3 is acts as a network modifier from 740 cm-1. The oxygen packing density (OPD) obtainedfrom density values shows an increase in the packag of the glasses network as a consequence of these results.

Study of environmentally friendly routes to produce MXenes

Vinícius dos Passos de Souza[1], Sydney Ferreira Santos[1], Rafael Kenji Nishihora[1] [1]Universidade Federal do ABC

e-mail: passos.souza@aluno.ufabc.edu.br

MXenes are 2D compounds that hold enormous potential for several technological applications, particularly in energy conversion and storage [1]. Despite their potential uses, producing these materials with high quality, i.e. contamination-free and defect-free lamellas efficiently exfoliated and delaminated, is a challenging task. Moreover, it is essential to develop environmentally friendly routes of exfoliation and delamination of the precursor MAX phase to obtain MXenes with adequate properties since the classical routes involve the use of concentrated fluoridric acid solutions. In this study, we investigated new synthesis protocols for producing the Nb2CTx MXene from the Nb2SnC MAX phase. The current literature suggests that obtaining a Sn-free MXene is challenging. To address this issue, we developed a new synthesis protocol based on the optimized routes designed for the Ti3AlC2 MAX phase. XRD, SEM- EDS, XPS, and TEM analysis indicated that Sn-free Nb2CTx MXene was obtained with good structural quality and chemical composition. These findings are significant for the advancement of high-quality MXene synthesis and may positively impact various application areas.

e-mail: passos.souza@aluno.ufabc.edu.br

MXenes are 2D compounds that have great potential for a variety of applications, including energy conversion and storage. However, their production with high-quality is challenging. The development of environmentally friendly delamination and exfoliation routes from the precursor MAX phase is crucial to minimize the impact of its production. Moreover, these synthesis protocols must be optimized for obtaining MXenes with the desired properties. This study focuses on the development of environmentally friendly routes to produce MXene with high structural quality and chemical composition for use in supercapacitors. New synthesis protocols were investigated for the production of Nb2CTx MXene from the MAX phase Nb2SnC, based on the optimized routes designed for the Ti3AlC2 MAX phase. The produced MXenes were analyzed by cyclic voltammetry and charge-discharge test, demonstrating potential for use in high-performance supercapacitors due to their unique properties of high electrical conductivity, high charge storage capacity, and high electrochemical stability. Thus, the development of environmentally friendly routes to produce high-quality MXene is a significant contribution to the advancement of MXene synthesis and the creation of more efficient and sustainable energy storage technologies. This study has a positive impact on research for new solutions for energy storage and environmental protection.

e-mail: rvasconceloscampos@gmail.com

The development of hydrogen storage methods is one of the important areas of research in the field of hydrogen energy, while metal hydrides combined with nanocatalysts are the preferred candidates for this. Among these catalysts, multi-walled carbon nanotubes (MWCNTs) have been widely studied with the aim of increasing the hydrogen storage capacity and mainly improving the hydrogenation kinetics. MWCNTs synthed by traditional methods have high aspect ratio (length/diameter), with a diameter in the order of magnitude of a few nanometers and length in the order of magnitude of micrometers, limiting their applicability in many situations. Mechanical milling is an interesting option to modify the morphology of this material, being able to generate short and open nanotubes. However, little is known about the behavior of this material when comminuted into finer particles and how the mechanical comminution process interferes with its morphology/properties. The objective of this work is to study the morphological and structural effects generated by mechanical milling in MWCNT. For this, the material was comminuted for different times (20 min, 1h, 2h, 6h, 12h and 24h) under mechanical milling and the samples were characterized by different techniques, such as SEM, RAMAN, XRD, EDS. At the end, we want to evaluate the appearance of defects and new carbonaceous structures, in addition to the change in surface area. As the mechanical milling time increased, SEM identified that after 6 hours it was no longer possible to identify the tubular morphology of the MWCNTs. The use of EDS allowed observing a decrease in the carbon content present in the samples due to the appearance of new elements, such as iron. Raman showed that the structure of MWCNTs was completely modified. From the XRD, it was possible to observe that the peaks widen with the increase of the milling time, indicating the amorphization of the material.

Study vibrational and thermogravimetric of $NH_4KCo(SO_4)_2(H_2O)_6$ mixed Tutton salt for thermochemical energy storage systems

Jardel Bruno de Oliveira Lopes[1], João Gomes de Oliveira Neto[1], Jacivan Viana Marques[2], Adenilson Oliveira dos Santos[2], Rossano Lang[3]

e-mail: jardeubruno@hotmail.com

Investigations of $X_2Y(SO_4)_2(H_2O)_6$ double-sulfated salts as thermochemical energy storage systems, where X(Y) is a monovalent(divalent) cation, have recently been reported [1]. In our first research on the $NH_4KCo(SO_4)_2(H_2O)_6$ mixed Tutton (named AKCoSH), the synthesis and a comparative structural study with its precursor salts were considered [2]. This work presents and discusses the vibrational property and the dehydration process of AKCoSH, which are important to phase change materials characterization aiming at the application in energy storage. Vibration modes analyses using FTIR and Raman spectra show contributions from the $[Co(H_2O)_6]^{2+}$ octahedral complex, $[SO_4]^{2-}$ tetrahedron, NH_4^+ cations, and coordination H_2O molecules. The assignments are based on those reported for the precursor Tuttons. The TG-DTA thermogram reveals that the AKCoSH is thermally stable from 300 up to 345 K. The first mass loss event is accompanied by an intense endothermal peak ascribed to salt dehydration. Complete rehydration was observed after 24 h. These results suggest the thermochemical application range using the AKCoSH. Three other thermal events (two Endo and one Exo between 495 and 600 K) in the DTA curve are observed; both are associated with mass loss stages. The attributions comprise the decomposition of an anhydrous compound and structural reorganizations. A crystalline phase transformation is supposed to arise due to the exothermal process around 600 K.

The development of products and technology is closely tied to the production of environmentally-friendly fuels, and one such strategy that has been employed is the use of photocatalysis to generate hydrogen from water. [1]. SrTiO3 has been widely studied as a semiconductor facilitator of photocatalysis reactions using sunlight, however, it has a band gap of 3.2 eV which causes it to absorb light only in the ultraviolet range (100-400 nm) meaning 4 - 5% of the solar spectrum [2]. Doping with transition metals such as Cr3+ increases light absorption in the visible range [3] and brings us promising results in the generation of H2. For this purpose, we have produced SrTiO3 semiconductors doped with Cr3+, and later, making use of the segregation effect, the material is decorated with Rh CrOx particles. The UV-vis spectroscopic analysis shows that RhCr/SrTiO3:Cr3+ has higher absorbance than the pure and Cr3+ doped material in the 400-700 nm range. The newly synthesized catalyst was able to produce 500 times more H2 (˜500 ·Mols after 5 hours of reaction) than the material only doped with Cr3+. The artificial photosynthesis reactions are conducted using a Xe lamp coupled with a 1.5 G AM filter in order to simulate the solar light.

Carbon capture, utilization, and storage (CCUS) has been widely considered as a relevant strategy to reduce CO_2emissions [1]. For such application, ionic liquids (ILs) are known as promising materials for CO_2capture, and are less corrosive and volatile when compared with traditional amine-solvent processes [2]. However, a problem associated with these materials is their high cost, enhancing the search for new cheaper ILs that could maintain this materials advantages over benchmark technologies. Surface-active ionic liquids (SAILs) constitute a particular class of ILs that contain long hydrophobic chains in the cation, anion, or both [3]. This type of structure can provide water miscibility as well as cost reduction when compared with traditional ILs, such as 1-butyl-3-methylimidazolium bis(trifluoromethylsulfonyl)imide ([bmim][NTf_2]), one of the most studied ILs for CO_2capture. However, there are only a few studies about CO_2capture using SAILs. In this context, the present study aims the development of a series of SAILs using [TBA^+] or [$bmim^+$] as cations, and surfactant anions, and to compare their CO_2adsorption with [bmim][NTf_2]. The experiments showed that at 50 bar of pressure and 50 °C of temperature, the combinationof TBA as cation and lauryl ether sulfate (SLES) as anion resulted in adsorption values of101 gCO_2/kg IL, better results in comparison to the more expensive similar SAIL [bmim][SLES] (61 gCO_2/kg IL). In addition, these results are similar to [bmim][NTf_2] CO_2sorption performance (111 gCO_2/kg IL) allowing to conclude that the use of SAILs for CO_2capturing are promising and potentially viable.

Hydrogen has great potential as a primary energy vector for economic decarbonization because it provides through renewable energy sources[1]. So far, nickel-based efficient electrocatalysts for hydrogen production remain non-highly active towards the hydrogen evolution reaction. Here we investigate the surface composition effects of the dispersed Ru atoms on Ni electrocatalysts towards the rate of hydrogen evolution reaction in alkaline media. Deposited Ru atoms interact on nickel sites, leading to enhanced catalytic properties and, consequently, increase the adsorbed-hydrogen surface coupling reaction (Volmer step)[2] when compared to bare Ni catalysts. Although promised effects, the specific activity drops upon the limit concentration due to the formation of larger Ru particles on Ni surface.

Energetic transition took place in global discussions highlighting the need to find renewable sources to produce biofuels. Lignocellulosic biomass might be an alternative to produce biofuel by a bunch of reactions. This process requires a set of reactions to produce these chemicals, including furfural condensation. This reaction is significant because it can enhance the furfural carbon chain, producing the trans-4-(2-furyl)-3-buten-2-one, applied mainly as fuel additive and precursor for biofuel synthesis. Nevertheless, this reaction needs an acid or basic catalyst, in that aspect, biochars are sustainable materials that might be applied for that purpose, since they obtained from biomass pyrolisis. In this work, we propose the application of syngonnium (Syngonium podophyllum) biochar as a catalyst for furfural condensation reaction.1 The biochar was synthesized by calcination in the air atmosphere of milled syngonnium at 350 °C for 2 hours.2 Several techniques characterized the biochar structure. Elemental analysis and FTIR analysis confirmed that biochar presents the expected organic structure, containing aromatic groups, C-O bonds, and carboxyl and phenolic groups. DRX and FRX analysis showed that some inorganic compounds are present in the structure as ashes, composed mainly of calcium oxide and carbonate. These compounds are relevant for catalysis since they confer basicity for this material, and this basicity value (2,02 mmol/g) was also quantified by titration.2 Further characterization and catalytic evaluation still need to be performed to evaluate this material''s performance. However, this material showed a considerable potential to be applied in condensation reactions since it has many basic sites in its structure. e-mail: geraldo.nery@unesp.br

Zeolitic framework in which the aluminum atom is replaced by transition metals with octahedral-pentahedral-tetrahedral coordination is known as OPT materials. Therefore OPT materials OPT is built up with a mixed crystallographic structure with tetrahedral silicon atoms and penta or octahedral coordinated transition metal atoms.[1]

Propylene is a basic start-point molecule for a large of important products productions, such as: Acetone, acrolein, polypropylene, and other industrial products. [2] One way of propylene production is through heterogeneous catalytic propane dehydrogenation [3]. In this study three novel OPT materials containing Cromium (Cr), Niobium (Nb) , Tin (Sn) and vanadium (V) were synthed using a set surfactant polymer as structure directing agents. The materials were characterized by X-Ray Diffraction (XRD); Fourier-Transform Infrared Spectroscopy (FT-IR); and Transmission Electronic Microscopy (TEM). The catalytic properties of these OPTs materials were tested in a typic fixed-bed quartz reactor at continuous flow. The catalysts were were studied in their as made and H2 reduced forms. The XRD patterns indicated the formation of pure and crystalline structure of the OPTs materials. The spectra of FT-IR the interaction between SDA and the polymeric chains of OPT materials. The SEM images showed the morphologic of theses crystals and TEM images indicate the formation of mesoporous. The catalytic results indicate all theses materials have a potential as heterogeneous catalysts to propane dehydrogenation. The H2 pre-treatment increase the propane selectivity.

Hydrogen is a versatile and clean energy carrier, and its use can supply the world''s energy demand. However, hydrogen generation is still mainly based on fossil fuels [1]. A hydrogen storage material that generates hydrogen on demand is sodium borohydride (NaBH4), and its hydrolysis requires the presence of a catalyst. Among catalysts for hydrogen production, Metal-Organic Frameworks (MOFs) have attracted attention, due to their large surface area and active sites [2]. In this work, NiCo-BDC was synthetized by impregnating nickel(II) nitrate solution onto Co-BDC and used for dehydrogenation of NaBH4. The MOF was characterized by FTIR, PXRD, and SEM-EDS. NiCo-BDC exhibited a pure crystalline phase, high hydrogen generation rate (707.15 mLmin-1gcat-1, 46 °C) and good activation energy (54.57 kJ mol-1). NiCo-BDC also presented high stability, having catalytic activity after 10 cycling tests.

The present work illustrates an one-step synthesis method of graphitic carbon nitride grafted nickel cobalt oxide using pyrolysis method. The as-prepared nanocomposites exhibit high specific surface area and excellent electrochemical performances for supercapacitor applications [1]. In this work $NiCo_2O_4$/g-$C_3N_4$was fabricated at temperatures of 350°C, 450°Cand 550°C. Each temperature creates a new material coated on nickel foam as base electrode in the construction of a high-performance supercapacitor. The three materials were characterized by FESEM, XRD and FTIR techniques. FESEM imaging confirmed thatthe materials have a nanoscale structure with some porosity and high surface area, allowingions to move between the electrode and the electrolyte, turning the reactions faster. The $NiCo_2O_4$/g-C_3N_4-350°C, $NiCo_2O_4$/g-C_3N_4-450°C and $NiCo_2O_4$/g-C_3N_4-550°C electrodes were characterized by electrochemical methods such as cyclic voltammetry, charge-discharge test and electrochemical impedance spectroscopy. The $NiCo_2O_4$/g-C_3N_4-350ºC, $NiCo_2O_4$/g-C_3N_4-450ºC and $NiCo_2O_4$/g-C_3N_4-550ºC electrodes showed specific capacitances of 268.71F/g, 86.04 F/g and 54.15 F/g respectively at a current of 0.5 A/g. The fabricated materials presented a higher performance, since it combines the advantages of all components: good conductivity, good electrochemical performance and pseudocapacitive properties [2].

This work describes the synthesis of nickel oxides grafted on graphitic carbon nitride nanosheets through a simple synthesis. The as-prepared was coated in carbon cloth (substrate) as electrode for supercapacitors applications. Morphological characterization was performed by FESEM technique which confirmed the presence of NiO/GCN-NS in the sample composition and its high surface area. Electrochemical methods such as cyclic voltammetry and charge-discharge test were performed to demonstrates the good electrochemical performance of the material for supercapacitors applications. The electrode showed good specific capacitances of 50 mF/g at a current density of 2 mA/g. This study shows that carbon cloth electrodes coated with NiO/GCN-NS contribute to supercapacitor applications that require good energy storage and present relevant mechanical flexibility of the material.

Synthesis, characterization and hydrothermal reduction of graphite oxide to obtain graphene sheets

RONNY FRANCISCO MARQUES DE SOUZA[1], Winandy Araújo Freire[1], José Adonias Alves de França[1]

[1]Instituto Federal de Educação, Ciência e Tecnologia de Alagoas

e-mail: ronny.souza@ifal.edu.br

Graphene is an allotrope of carbon that has attracted widespread interest as it is a versatile material capable of behaving like a liquid crystal [1] and exhibiting remarkable transparency, mechanical, thermal and electrical conductivity [2]. This work aimed to obtain graphene sheets from the reduction of graphite oxide by hydrothermal route. The graphite oxide synthesis was achieved following the modified Hummers methodology [3] conducted under temperature control, below -10 °C, given the exothermic nature of the reduction reaction. To investigate the nematic phase, that is, the liquid crystals, a 100 W power reflector and a polarizing film were used, keeping it at a standard angle. For this purpose, a photographic camera and a polarizing lens were used. After sending the material was isolated. The presence of oxygenated organic functions in the reaction product was confirmed by infrared spectroscopy. In solution, proceed with the reduction of graphite oxide in a hydrothermal reactor, for 24 hours at a temperature of 170 °C. It was observed that the appearance of liquid crystal depends on the concentration, as the concentration of graphene sheets increases, more prominence gains this property. The presence of oxygenated groups in the material obtained after hydrothermal reaction was lower compared to the standard graphite oxide. Spectrum analysis also showed an increase in the band of C=C bonds, after the hydrothermal reaction, when compared to the standard graphite oxide band, indicating reduction of the material.

e-mail: marcos.roberto@ufabc.edu.br

NaNbO3 has been shown to be a very promising catalyst for the photoelectrochemical disproportionation of water and CO2 photoconversion [1, 2]. However, in order to increase its catalytic efficiency, it is necessary to improve the lifetime of the photogenerated charges and the modulation of its visible light absorption capacity. These properties, in turn, are associated to morphological and structural control. This work aims to study the optimization of the synthesis of NaNbO3, through microwave-assisted hydrothermal routes [1, 2]. The efficiency was improved through in situ polymerization of graphitic carbon nitride (g-C3N4), as well as adding platinum nanoparticles as co-catalyst in order to reduce the recombination effects of photogenerated charges on the material. SEM images show that R1 and R2 gave rise to 1D wire-like species. Despite this, the MET images, suggest a distinct mechanism of growth of these structures. The growth mechanism apparently impacts the crystal structure of the resultant material, which show an orthorhombic phase with subtle changes, which may indicate the presence of spurious phases. These variations impact the way NaNbO3-R1 and R2 interact with g-C3N4 and Pt. Consequently, the photoelectrochemical response of the investigated materials.

MXenes is a family of 2D layered compounds with outstanding properties derived from their layered structures, complex chemical bonding and surface terminal groups. Therefore, these materials have been considered highly promising for several technological applications, particularly those related to energy storage and conversion such as rechargeable batteries, fuel cells, electrolyzers, solar cells, supercapacitors, etc. To fully understand the structural features of such materials and the relationships with the properties of interest, advanced characterization techniques must be employed. In this work, MXene compounds ($Ti_3C_2T_x$and Nb_2CT_x) obtained by different synthesis routes were characterized by transmission and scanning-transmission electron microscopy. The characterization was performed using a transmission electron microscope, ThermoFisher Scientific model Talos F200X equipped with a 4 in-column SDD EDX detectors. The investigated samples were synthed employing different types of fluoride salts in the exfoliation process. Particularly for Nb_2CT_xMXene, obtained from the exfoliation and delamination of the Nb_2SnC MAX phase precursor, the synthesis protocol is critical since obtaining Sn-free MXenes and its characterization are challenging tasks. The microstructural features of the investigated MXenes were assessed particularly concerning the presence of crystallographic defects. STEM was also important to perform chemical mapping of the investigated samples. The interplay between the microscopy results and synthesis protocols are depicted allowing designing more appropriate routes to synthe and functionalize the investigated compounds.

The influence of PVP molecular weight in the synthesisof silver nanowires using a salt-assisted polyol method

Barbara Perez Gonçalves Silva[1], Larissa Otubo[1]

[1]Instituto de Pesquisas Energéticas e Nucleares (*CECTM*)

e-mail: barbara_pe@hotmail.com

In the last decades, the demand for new materials to be used in electronic devices has increased. Among the materials that can be used in transparent conductive films (TCFs), are the silver nanowires (AgNWs). This class of material, when supported in glass or PET, e.g., has good conductivity, thermal and mechanical properties and also high transparency. In this work, the AgNWs were synthesized using the polyol method assisted by a salt and the influence of molecular weight of the capping agent polyvinylpyrrolidone (PVP) in the morphology and structure of Ag crystals was investigated. Different molecular weight of PVP (40 K, 120 K, 360 K and 1300 K MW) was used in the synthesis. The surface morphology of the products was observed by scanning electron microscopy and atomic force microscopy. The phase composition and structure were analyzed by X-ray diffraction (XRD) and the XRD patterns diffraction peaks correspond with the face-centered-cubic (fcc) crystalline phase of silver. Transmission electron microscopy was used to analyze the crystal structure, and UV-visible spectroscopy was used to follow the formation of Ag structures. The results indicate that PVP and its chain length have an important role in the formation of silver nanocrystals due to the adsorption and steric effects [1] and as high is the molecular weight of PVP, longer and thinner are the AgNWs as observed by other authors [2]. Different morphologies were obtained when changing the size of PVP chain. For smaller MW of PVP, particles and short wires were formed. Increasing the MW, nanorods and pyramidal particles were formed, and finally, forming nanowires when using the highest MW PVP of the experiments. Improving the aspect ratio of silver nanowires is important to construct TCFs, since the conductivity and transparency properties are improved when they are thinner and longer. Ref.: [1] Song, YJ., et. al, Nanoscale Res. Lett., 9, 17 (2014). [2] Yuyue Guo,et al, Inorg. Chem. Comm., 128, 108558 (2021).

Tungsten trioxide fibers with enhanced photoelectrocatalytic activity

Beatriz Caetano Benuto[1], Leonardo Jesus de Campos[1], Roberta Antigo Medeiros[1], Roberto de Matos[1]

[1]Universidade Estadual de Londrina (*Química*)

e-mail: beatrizcbenuto@gmail.com

Tungsten trioxide (WO_3) with the band gap of 2.4-2.8 eV, is one of the most important semiconductors, especially for electronic devices, gas sensors, photocatalysis, and water splitters [1,2]. Compared with conventional methods, electrospinning is a versatile method and can produce continuous nanod oxide fibers [2]. In this work, we reported the exploration of photoanodes based on WO_3fibers on FTO through a simple electrospinning strategy. Firstly, 0.2 g of polyvinylpyrrolidone (PVP, Mw 1300000) was dissolved in 0.6 mL of ethanol and 2.0 mL of DMF with vigorously stirring for 2 h. Then, 1.0 g of $WCl_6$was added to the above solution and continued to be stirred for 1 h. The solution was transferred to a plastic syringe for the electrospinning process, under 15 kV, rate of 0.36 mL/h, 18 cm from the collector, with ambient temperature and relative humidity at 20 °C and 45 %, respectively. After, the samples were calcined at 500 °C for 1 hour (2 °C/min) [3]. Fiber morphology and structure were studied using X-ray diffraction and scanning electron microscope. The photocurrent activities of the as-prepared samples are evaluated by voltammetry and chronoamperometry measurements performed in Na_2SO_4solution (0.1 mol L^{-1}) under visible light and interfacial properties by electrochemical impedance spectroscopy. Experimental results demonstrate the WO_3nanofibers formation and photocurrent density can be up to 0.25 mA cm^{-2} at 1.0 V vs. Ag/AgCl. The Nyquist plots of electro-spun samples showed a smaller radius which indicates a lower resistance to charge transfer and higher transmission efficiency compared with WO_3particles. Therefore, current work might open up an avenue to develop novel and efficient photoelectrodes.

Unlocking the Potential of Deep Eutectic Solvent in ZnSe Nanoparticle Synthesis via Hot Injection Methodand Factorial Design

Julia Gelinski Tallmann[1], Tatiane Pretto[2], Marcos Jose Leite Santos[3]

[1]Universidade Federal do Rio Grande do Sul (*Escola de Engenharia*) , [2]Universidade Federal do Rio Grande do Sul (*Instituto de Química*) , [3]Universidade Federal do Rio Grande do Sul (*PGCIMAT - Programa de pós-graduacão em ciência dos materiais*)

e-mail: juliatallmann@hotmail.com

Zinc Selenide (ZnSe) is a widely known semiconductor in the literature, but minor is known about their synthesis in Deep Eutectic Solvent (DES), which enables biological application. [1,2] The optical and electrical properties of ZnSe, are crucial to its application, depending on the size of its nanoparticles, which can be controlled through the hot injection method. In this study, ZnSe synthesis in DES was carried out using a 24 factorial design in duplicate. The parameters evaluated were the reaction temperature (50 ºC or 80°C), reaction time (1or 5 min), solvent (ethaline or glyceline), and atmosphere (ambient or inert). First, 10 mL ofDES was prepared, using choline chloride:ethylene glycol 1:2 (ethaline) or choline chloride:glycerin 1:2 (glyceline), followed by the addition of 1 mmol of zinc acetate. Then, the systemwas heated to the desired temperature. Reaching this temperature, a solution of reducedselenium was injected, and the time of reaction was initialized. The reduced selenium wasprepared in an inert atmosphere by adding 1 mmol of elemental selenium in a 5 mL aqueoussolution of 2 mmol sodium borohydride. By the end of the synthesis, each sample was separated into two aliquots, half of which were washed and redispersed in ethanol, and theother half, kept in DES without washing. XRD analysis in DES presented the formation ofZnSe, while the washed solutions presented selenium, also. The UV-Vis spectra showed absorption around 400 nm and a bandgap of 3.0 eV. The materials presented fluorescenceemission around 700 nm. From now, DLS, SAXS, and TEM characterizations will be performed to observe the particle size. Finally, it will be possible to evaluate the effects ofthe studied parameters and conclude how DES helps to stabilize the structure and size of the particles.

Biomass is a renewable resource available on a large scale, which can be used as biofuel, and for its better application, characterization is necessary. Among the important parameters to evaluate the potential of a fuel is the Calorific Value, defined as the amount of energy released in the complete combustion. In this context, the work presents the comparative evaluation of the Higher Heating Value (HHV) of Neem seed husks (Azadirachta indica) in natura form and compacted form called briquette. Studies show that Neem biomass has a significative HHV, which represents a viable option as a renewable energy source, producing less greenhouse gas emissions compared with fossil fuels. To the calculation of the HHV was used an equation based on the results of the proximate analysis: HHV = 0.3536x(% FC) + 0.1559x(% VM) − 0.0078x(% A) [1], in which FC is the fixed carbon content, VM is the volatile matter content, and A is the ash content. The HHV results for Neem seeds and briquette were 17.82±0.29 MJ/kg and 17.60±0.17 MJ/kg, respectively. The briquette production from Neem seeds did not show significant variation in the HHV. However, the briquette facilitates the transport and storage of biomass for further use. Another possibility to increase the HHV is to prepare blends using different biomasses. Finally, the application of Neem seed husk did not change the properties during the briquette production process, being a favorable characteristic of this biomass.

Use of sugarcane bagasse to obtain structured aluminain the replica method for carbon and H_2 production

Alson David Rodrigues da Silva[1], Rayssa Jossanea Brasileiro Motta[1], Rusiene Monteiro Almeida[1]

[1]Universidade Federal de Alagoas

e-mail: alson.silva@ctec.ufal.br

Sugarcane bagasse (lignocellulosic material) is the most abundant solid residue from sugar and alcohol production, in which it is predominantly destined for burning to generate energy. In order to minimize this burning, many studies highlight an alternative use for this waste. Thus, in this work, the sugarcane bagasse was used in the replica method for alumina production with predetermined dimensions. Sugarcane bagasse samples were impregnated with an aqueous solution of $Al(NO_3)_3.9H_2O$, pressed at 13 kgf for production of cylindrical green bodies followed by drying at 75 °C and calcination at 1500 °C. The samples obtained after calcination were impregnated with different concentrations of Ni (5%, 10% and 20% w/w), resulting Ni anchored in structured alumina, Ni/Al_2O_3-S samples,followed by characterization by SEM, XRD, TPR, nitrogen fission at 77 K and TGA. In themicrographs, it was observed that Al_2O_3-S maintained the morphological characteristics of the test body and the alpha alumina phase presence (XRD). The Ni/Al_2O_3-S samples showeda reduction temperature in the range of 370 - 650 °C, without the presence of nickelaluminate (XRD). The samples were submitted to methane decomposition reaction at 500 °Cfor production of carbon and $H_{2(g)}CO_x$free. The tests were conducted in a continuous flowreactor with passage of the gas mixture of $N_2:CH_4$(6:1 v/v) in a flow of 35 mL. min^{-1}, for 30 min. The samples of $5Ni/Al_2O_3$-S, $10Ni/\ Al_2O_3$-S and $20Ni/Al_2O_3$-S showed conversion of methane into carbon yields 11, 45 and 49%, respectively.

$WO_3/BiVO_4$ side-by-side electro spun heterojunction for photoelectrochemical water splitting

Beatriz Caetano Benuto[1], Roberta Antigo Medeiros[1], Roberto de Matos[2]

[1]Universidade Estadual de Londrina (*Química*) , [2]Universidade Estadual de Londrina (*QUIMICA*)

e-mail: beatrizcbenuto@gmail.com

The generation of hydrogen fuel by a photoelectrochemical cell (PEC) can be considered a green hydrogen production route when compared to other processes [1]. In this work, we reported the preparation of photoanodes based on $WO_3/BiVO_4$side-by-side fibers on FTO. Firstly, 0.2 g of Polyvinylpyrrolidone (PVP, Mw 1300000) was dissolved in 0.6 mL of ethanol and 2.0 mL of DMF with vigorously stirring for 2h. Then, 1.0 g of $WCl_6$was added to the above solution and continued to be stirred for 1h to form a blue solution. [2]. The $BiVO_4$precursor spinning solution was prepared adding 1.21 g of $Bi(NO_3)_3$. $5H_2O$, 0.35 g of PVP, and 0.66 g of $VO(acac)_2$to 1.0 mL of acetic acid, 1.6 mL of ethanol, and 1.4 mL of DMF, which was then stirred for 2h to form a green solution [3]. The two solutions were transferred to syringes for side-by-side electrospinning, under 15 kV, total rate of 0,36 mL/h, 18 cm from the collector, with ambient temperature and relative humidity at 20 °C and 45 %, respectively. After, the samples were calcined at 500°C for 1h (2°C/min). Fiber morphology and structure were studied using X-ray diffraction and scanning electron microscope. The photocurrent activities were evaluated by voltammetry and chronoamperometry in Na_2SO_4(0.1 molL-1) under visible light and interfacial properties by electrochemical impedance spectroscopy. Results demonstrate the $WO_3/BiVO_4$nanofibers formation and photocurrent density can be up to 80 μAcm^{-2}at 1.2 V vs. Ag/AgCl. The high photoelectrocatalytic properties could be attributed to the successful establishment of $BiVO_4$and WO_3heterojunction with lower resistance to charge transfer and higher transmission efficiency compared with pure $WO_3$and $BiVO_4$fibers.

J-Materials for application in smart devices for energy storage and conversion

Crystal growth from the melt: some fundamentals of growth and applications for energy conversion

Manuel Henrique Lente[1]

[1]Universidade Federal de São Paulo (*Departamento de Ciência e Tecnologia*)

e-mail: mlente@unifesp.br

Advanced functional materials are fundamental to high-efficiency energy conversion devices. In particular, compared to polycrystalline bulk materials, single crystals present much higher physical properties thus, being of a strong interest in the high technology industry. The crystal manufacturers demand, in turn, the production of crystals with highpurity, a high degree of perfection, large size, and industrial-scale mass production. Fromthe basic science point of view, single crystals are also excellent systems for investigating fundamental principles and for discovering novel properties. In this context, over the last100 years, oxide bulk single crystals produced by different methods have been massively used for many purposes. In this work, it will be reviewed some fundamental aspects of boththe heat transfer theory and mechanisms of growth of oxide bulk single crystals producedby vertical Bridgman-Stockbarger (VB-S) route. It will be shown that such route demandsoptimized growth conditions to produce high-quality crystals for achieving higher conversion efficiency materials. Such conditions include a complete previous analysis of thethermal properties of the precursor oxides, the characterization of the temperature gradientin the region of the liquid-solid interface, a suitable choice of the dimensions of the crucible,and the growth rates, among other issues. In particular, such approach will be presented and discussed, focusing on the growth of ferroelectric single crystals. The optimization ofthe structural and piezoelectric properties as well as the potential induction of novel properties for energy conversion allowed in multiferroic/ferroelectric crystals by co-doping strategy will be also discussed.

Acknowledgements: The author would like to thank the financial support from FAPESP (grants 2017/13769-1; 2019/14688-0) and CNPq (grant 409780/2021-9).

Room-temperature optical and magnetoelectric response in A and B site co-doped layer-structured Aurivillius ceramics

e-mail: eiras@df.ufscar.br

Ferroelectric oxide materials have been subject of innumerous investigations, due to their superior physical features, that make them ideal for developing new multifunctional materials. Complex ferroelectric oxides offer exceptional options to tune physical properties, such as optical and multiferroic, with high temperature stability. Among them, due to their lead-free nature, bismuth titanate (Bi4Ti3O12)-based oxides, belonging to the Aurivillius family, have recently gained interest viewing to improve photoferroelectric and magnetoelectric properties. Bismuth titanate structures, composed of three alternating (Bi2Ti3O10)2- perovskites layers sandwiched between two of fluorite-like bismuth oxide (Bi2O2)2+ layers, can present high stability even after significant chemical doping. In this work the influence of iso- and heterovalent doping in the structural, dielectric, optical absorption, ferroelectric, magnetic and magnetoelectric properties of Aurivillius structures (bismuth titanate-BIT based ceramics of Bi3.25A0.75Ti3-x(Co, Fe)x/2O12, where A=La, Nd or Sm and x=0, 0.1, 0.2, 0.3, 0.4), have been investigated. Single phase bulk ceramics were synthed through the conventional oxide mixture process. It was observed that heterovalent (Co, Fe) co-doping promotes a decrease in the band gap (red shift), compared with the Bi3.25A0.75Ti3O12 matrix, still maintaining a ferroelectric spontaneous polarization, and induce room temperature multiferroic state. These results are discussed and correlated with changes in the electronic structure, octahedral distortions (tilting angles and bond lengths), and oxygen vacancies formation, Acknowledgments: The authors gratefully acknowledge the Brazilian funding agencies CNPq and FAPESP.

The role of line defects on the physical properties of BiFeO3 nanoparticles

Ivair Aparecido dos Santos[1], Eduardo Azzolini Volnistem[2], Roger Carvalho Oliveira[1], Luiz Fernando Cótica[2], Gustavo Sanguino Dias[2]

[1]Universidade Estadual de Maringá (*Física*) , [2]Universidade Estadual de Maringá (*Departamento de Física*)

e-mail: iasantos@dfi.uem.br

Bismuth ferrite ($BiFeO_3$ - BFO) is a perovskite structured (ABO_3) multiferroic magnetoelectric compound that, due to its simultaneous ferroelectric and antiferromagnetic ordering at room temperature, is one of the most promising candidates for applications in advanced electronics. However, the presence of a magnetic spin-cycloid with a period of 62 nm suppresses its long-range magnetic response. Several strategies can be applied to suppress or break the spin-cycloid to release the BFO magnetization, as doping/substitutionof iso or heterovalent ions in specific sites of the perovskite cell, or nanostructuration. Inthis context, high-energy cryo-milling was recently applied for synthesizing BFO nanopowders with controlled crystallite s and internal strain, resulting in an unusual non-linear and enhanced magnetic response that differs from that widely reported for bulk BFO. In this contribution, the role of line defects, as edge and screw dislocations, on the overall physical properties of multiferroic magnetoelectric nanoparticles is discussed taking BFO nanoparticles as a study model. It is pointed out that the control of the dislocation density in 2D or 3D nanostructures can be used as efficient tool to control physical properties and tailor specific technological applications.

Application of the GPA tool in Ferroelectric Prototypes Analysis

e-mail: vfreitas@unicentro.br

The tool, Geometrical Polarization Approach" (GPA), has recently been developed and usedto analyze the polar nature of Dielectric Materials with Perovskita structure and quantifytheir main resulting properties [1]. The GPA tool aims to reveal intrinsically characteristicsof polar matters still in powder, allowing to know their properties before the costly processto synthesize dense ceramic bodies. In this approach, the intrinsic polarization, as a signature of the polar state, is obtained from the off centering position of nominal negativeand positive electric charges into a unit cell, which is achieved from the relative atomicpositions of cations and anions by diffraction experiments [1]. Important characteristicshave been revealed comparatively through its use, such as polar responses to externalstimuli. In this work the GPA tool was applied to materials under extreme external stimuli,such as high pressures. Different ionic modifications were also investigated within the unitcells and their respective responses to polarization [2]. We analyzed complex ceramic, withmodifications in the cationic atomic sites of perovskites. Finally, different theoretical arrangements for Rietveld refinement were proposed to investigate local polarization situations and compare them with the global one.

Developing a Highly Sensitive Sensor for Low Intensity and Low Frequency Magnetic Fields using $CoFe_2O_4$ and PZT Fibers

Lilian Nunes Pereira[1], Gustavo Sanguino Dias[2], Ivair Aparecido dos Santos[3], Luiz Fernando Cótica[2]

[1]Universidade Estadual de Maringá, [2]Universidade Estadual de Maringá (*Departamento de Física*) , [3]Universidade Estadual de Maringá (*Física*)

e-mail: liliannunespereira@gmail.com

The magnetoelectric sensor is a class of magnetic sensors with high sensitivity that suitable for the measurement of low-frequency weak magnetic fields. This study presents the synthesis and characterization of a magnetoelectric composite material composed of $CoFe_2O_4$and PZT fibers, with the aim of developing a sensor for low intensity and low frequency magnetic fields [1]. The composite exhibits a strong magnetoelectric coupling, allowing for the conversion of a magnetic field signal into an electrical signal. The resulting sensor is highly sensitive and able to detect magnetic fields with low intensity and frequency, making it ideal for measuring biological magnetic signals such as those generated by heartbeats. We demonstrate the feasibility of using this magnetoelectric composite as a magnetic field sensor through experimental measurements and simulations. Our results indicate that this sensor has great potential for use in medical applications, including non-invasive monitoring of cardiac activity. Overall, the development of this magnetoelectric composite provides a promising avenue for the advancement of magnetic field sensing technology.

The authors would like to thank Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq), Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES) and Fundação Araucária de Apoio ao Desenvolvimento Científico e Tecnológico doEstado do Paraná Brazilian agencies, for providing financial support.

Energetic and electronic properties of metal-organic frameworks doped with transition metals: A hybrid functional study

Walter Orellana[1]

[1]Universidad Andrés Bello (*Departamento de Física*)

e-mail: worellana@unab.cl

Metal-organic frameworks (MOFs) are crystalline porous solids with large surface areas formed by coordination bonding between organic ligands and metal centers (ions or clusters). Owing to their structural diversity and functional adjustability, these nanoporous materials have been extensively investigated for applications in energy storage, gas separation, and sensing. Tens of thousands of unique structures have since been synthesized. However, only a few works on electronic structure and transport properties have been reported. Here, we use DFT hybrid functional calculations to explore the incorporation of transition-metal impurities in the iconic metal-organic structure Zn4O(BDC)3 (BDC=benzene-1,4-dicarboxylate), known as MOF-5 or IRMOF-1.[3] We focus on the electronic structure, formation energy, and conductivity of MOF-5 doped with transition metals M occupying a Zn site (M=Sc, Ti, V, Cr, Mn, Fe, Co, Ni, Cu, and Al), exploring a possible doping mechanism. Our results show that MOF-5 is an insulator with a fundamental band gap of 4.8 eV, where the frontier orbitals, namely the valence band maximum (VBM) and the conduction band minimum (CBM) are associated with the ligands. The incorporation of metal impurities in MOF-5 introduces defect states in the band gap, changing its electronic properties while preserving the structure. Formation energy calculations indicate that Sc and Al are the most stable impurities exhibiting donor levels close to the conduction-band minimum, remarkably decreasing the band gap to around 0.2 eV. Whereas Cr, Fe, and Ni are stable in a neutral charge state, inducing midgap levels. Our results suggest that selected metal dopants can induce p-type conductivity. The control of the band gap and semiconducting properties observed will render MOF-5 a wide range of applications in electronic and optoelectronic, and sensing devices. This work was supported by the FONDECYT Project 1230138 and the Anillo Project ANID/ACT 210059.

Exploring the phase transitions of low-dimensionalmetal halide perovskites

e-mail: ayala@fisica.ufc.br

Low-dimensional metal halide perovskites have shown remarkable properties, making them promising materials for optoelectronic applications such as photovoltaics, light-emitting diodes, and lasers. In this contribution, we present recent studies on the phase transitions and properties of these materials using techniques such as single-crystal and synchrotron X-ray diffraction, as well as optical and vibrational spectroscopies, under varying temperature and pressure conditions. Distortions on the metal halide polyhedral network determine the excitonic states, favoring the production of self-trapped excitons (STEs). STEs play a crucial role in the phase transitions of these materials, especially in low-dimensional systems where confinement effects are more pronounced. The presence of STEs is correlated with the structural and optical properties, and their behavior depends on changes in temperature and pressure. Our results provide new insights into the relationship between the structureand electronic processes that lead to the unique optoelectronic properties exhibited by these materials. These findings can guide the optimization of perovskite-based optoelectronic devices by controlling the STE behavior.

e-mail: thissiana.fernandes@unifesp.br

Lead-based single crystals are widely recognized for their remarkable dielectric and piezoelectric properties. However, concerns about the impact of the extensive and continued use of Pb-based materials on the environment have led to the investigation of alternative piezoelectric compositions. Among these alternatives, lead-free single crystals based on (K, Na)NbO$_3$have shown great promise for substituting Pb-based materials [1]. In this study, soft (K, Na)NbO$_3$single crystals were grown using the Bridgman-Stockbarger method, and their physical properties were characterized. The XRD patterns of the crushed crystals showed a pure perovskite structure with an orthorhombic structure at room temperature, indicating a slight compositional shift compared to the precursor powder. The coefficients of thermal expansion of the single crystal were determined in different crystallographic directions using the dilatometric method for the first time, and the obtained values were compared to those of ceramics. The temperature dependence of the dielectric constant revealed two dielectric anomalies, corresponding to the ferroelectric-ferroelectric transition at 93 °C and the ferroelectric-paraelectric transition at 295 °C. The values of the dielectric constant at room temperature were found to be consistent with those reported in the literature for similar compositions.

Multidimensional Elemental and Molecular Analysis for Surface Interface studies

Patrick Chapon[1], Alice Stankova[1], Clyde Chmielinski[1], Igor Carvalho[2]

[1]HORIBA FRance, [2]Horiba

e-mail: patrick.chapon@horiba.com

Surface and Interface studies require the use of complementary analytical techniques as each instrumentation provides results based on the interaction of the investigated material with a probing medium [1]. Obtaining elemental and molecular information for different probing size and depth are especially crucial.HORIBA offers a Platform with multiple instruments able to tackle these complex analytical challenges. Glow Discharge relies on a plasma to sputter a representative area of a material and provides fast elemental depth profile with nanometer resolution [2]. Coupling GD and Raman microscopy allows to obtain molecular information at various depths with micrometer lateral resolution [3,4]. Applying the GD software ideal to follow transient signals to a simultaneous ICP instrument coupled with an electrochemical cell (AESEC technique) offers deep insight on dissolution mechanisms and metallic surfaces performances [5].We will illustrate the benefit of this Surface Platform for Elemental and Molecular Analysis with selected results on metallic parts for high temperature fuel cells, perovskite solar cells, hydratation of anodic films and DCL coatings on bipolar plates.

The magnetoelectric coupling in nanostructured systems has attracted interests mainly dueto possibility of integration between ferroelectricity and ferromagnetism through the handling of electric and magnetic order by cross coupling between electric and magneticfields. In this work, the fabrication process was investigated by the RF-Sputtering techniqueand the characterization of heterostructured multiferroic composite materials of Pb(Zr0.2Ti0.8)O3/CoFe2O4 were performed. The interface between phases has a significant role for the existence of coupling between the different phases, where variations of the ferroelectric and dielectric properties in the heterostructured system were correlated to strain and/or stress at the interface between the phases. It was also possible to determine the existence of magnetoelectric coupling, since an improvement of the ferroelectric properties was observed under the presence of a magnetic field of ~5 kOe. Finally, it was reported that the magnetodielectric coupling is enhanced in the dielectric dispersion region due to competition between the compressive stress in the PZT phase generated by CFO phase and the changes of electric polarization due to the ME coupling.AcknowledgementsThis work was supported by FAPESP (Grant numbers: 2020/06570-7 and 2017/13769-12) and CNPq (grant # 404538/2021-5).

Optimizing Parameters for $BiFeO_3$ Thin Film Formation via Dip Coating Deposition for Photovoltaic Applications

e-mail: lucianocd8@gmail.com

The advancements in thin film materials techniques have led to significant progress in understanding material properties, resulting in devices with increased durability, reduced waste material, and smaller size while maintaining high efficiency, especially for photovoltaic applications [1-3]. In this work, the deposition parameters involved in the dip coating technique were analyzed in search of a better way to obtain $BiFeO_3$(BFO) thin films for photovoltaic applications. The results of the parameter analysis showed that a better deposition is mainly related to the substrate cleaning method, drying temperature, and solution concentration. The optimized deposition parameters were used for a single-layer photovoltaic device, which exhibited a photoconversion of 0.98 mV. These results indicate that dip coating with optimized parameters is a promising route for thin film formation of BFO for photovoltaic devices.

Over the past few years, perovskite materials have emerged as strong candidates for replacing traditional silicon solar cells due to their high efficiency and low cost [1]. The parameters for the fabrication of photovoltaic devices using these materials are directly related to their photoconversion efficiency [2,3]. In this work, thin films of multiferroic perovskite $BiFeO_3$were synthed by dip coating technique, and the photoconversion efficiency was found to be strongly related to the temperature of deposition and the number of layers. Specifically, an increase in the number of layers from 10 to 20 resulted in a significant increase in photoconversion efficiency, from 0.77 mV to 0.98 mV, respectively.

Patrónite-based VS_4 Nanostructures: Fundamental Aspects and Applications in Lithium-Sulfur Batteries

Leandro Seixas Rocha[1], Jonathas Costa da Silva[1], Renato Barbosa Moreira[1], Rafael Oliveira de Figueiredo[1]

[1]Universidade Presbiteriana Mackenzie (*Escola de Engenharia*)

e-mail: leandro.seixas@mackenzie.br

Patrónite is a mineral formed by vanadium tetrasulfides (VS_4) in a crystalline structure of quasi-one-dimensional nanowires bonded by van der Waals interactions. Recently, VS_4nanostructures were synthesized on substrates of carbon nanotubes doped with nitrogen or reduced graphene oxides, with potential applications in lithium-sulfur battery cathodes. $VS_4$is a highly polar chalcogenide with strong interaction with lithium polysulfides (LiPS). It acts on the anchoring LiPS fragments, reducing the shuttling effect and increasing the battery lifespan. In this work, we investigate the electronic, magnetic, mechanical and structural properties of nanostructures based on VS_4. Intrinsic magnetic orders were observed in the nanowire, with phase transitions with plastic deformations. We also investigated the formation of native point defects in the VS_4nanostructures and LiPS bindings in these point defects. We show that vanadium tetrasulfides have interesting characteristics for applications in electronic and electrochemical devices, such as sulfur composite components in the cathode of lithium-sulfur batteries.

Polymers such as poly(vinylidene fluoride) (PVDF) and poly(lactic acid) (PLA) have been widely studied as biomaterials due to their biocompatible properties in contact with living tissues. In particular, PVDF presents piezoelectricity when in the β phase[1], such an effect favors bone regeneration and is even associated with the natural repair process of this tissue in living organisms [2]. When mixed with hydroxyapatite (HA), PVDF and PLA can form biphasic and triphasic composites with some electrical and biological properties similar to the bone tissues being potential candidates to be used as 4th generation of biomaterials in orthopedics and orthodontics. In the present work, composites of PVDF, PLA and HA in different concentrations were produced by 3D printing.Scanning electron microscopy (SEM) images indicate the formation of immiscible polymeric blends for the PVDF and PLA composites, which is altered with the addition of HAp in the sample, changing the blend to miscible. Furthermore, the addition of HAp promotes the bioactivity of the materials, which can be evaluated by SEM and Energy Dispersion X- Ray Spectroscopy (EDS). In addition, the printed samples have low contact angle indicating a high hydrophilicity of the material. Therefore, the composite presents great potential to be used in the future in biomedical applications.

Bismuth ferrite ($BiFeO_3$ - BFO) is a perovskite-structured multiferroic material that exhibits simultaneous ferroelectric and antiferromagnetic ordering at room temperature, making it a promising candidate for electronic applications. The magnetoelectric coupling in BFO arises from the complex interplay of spin, lattice, and orbital degrees of freedom. The magnetoelectric effect in BFO nanoparticles can be influenced by factors such as particle size, microstructure, and defects or impurities. Smaller particle sizes result in increased surface effects that impact the properties and coupling of magnetic and electric order parameters. Moreover, defects or strain can alter these interactions, leading to changes in magnetoelectric coupling strength. Cryomilling has been employed to synthesize BFO nanopowders with controlled crystallite sizes and dislocation density, resulting in an unusual non-linear and enhanced magnetic response. In this study, cryomilling was utilized to achieve low crystallite sizes and introduce high dislocation densities. Atomic Force Microscopy (AFM)-based techniques, such as Piezoresponse Force Microscopy (PFM) (with and without an external magnetic field) and Magnetic Force Microscopy (MFM), were applied to investigate the effects of size and dislocation density on ferroelectric, magnetic properties, and magnetoelectric coupling. This comprehensive investigation provides insights into the role of size and dislocation density in modulating the multiferroic properties of BFO nanoparticles and their potential applications in advanced electronic devices.

Spray pyrolysis as an alternative route to producing thermoelectric layers of Na_xCoO_2

e-mail: mgodoy@ufscar.br

Alternative energy sources and energy storage are currently essential issues for human development. Access to new technologies heavily relies on their maintenance, availability, and production costs. Additionally, an effective energy storage system and the generation of renewable energy work together to provide long-term solutions for the goal of a sustainable energy plant. As a result, one way to produce clean energy is by thermoelectric conversion of waste heat. We present a systematic analysis of thermoelectric oxide coatings produced by spray pyrolysis. Although it produces rough layers compared to other processes, this technology is cost-effective and adaptable for large-scale production. It is possible to develop polycrystalline $NaCoO_2$thin films at lower and higher crystalline conditions by controlling synthesis parameters, such as the molarity M of the precursor solution. Additionally, the annealing in the oxygen atmosphere improves the crystallinity and reduces the influence of oxygen vacancies. According to X-ray diffraction and Raman spectroscopy, the growth of γ-$NaCoO_2$phase maintains its crystalline symmetry even at high Na contents. Due to optical resonance conditions, Raman modes linked to oxygen in-plane motion can be seen depending on the excitation wavelength. The Seebeck coefficient and electrical resistivity fall as Na concentration rises in lower crystalline samples. As a result, when x= 1.5, a power factor of up to ~3,3 $\mu W/K^2m$ is achieved. Higher crystalline films have Seebeck coefficients up to 500 µV/K but with poor electrical conductivity.

Strategies for incorporation of polypyrrole as pseudocapacitive component in hybrid supercapacitors

Helinando Pequeno de Oliveira[1], Ravi Moreno A. P. Lima[1]

[1]UNIVERSIDADE FEDERAL DO VALE DO SÃO FRANCISCO (*Ciência dos Materiais*)

e-mail: helinando.oliveira@univasf.edu.br

The requirement for energy storage devices with mutual high energy and power density reinforced the research in new supercapacitors that combine pseudocapacitive components and electrical double-layer capacitance (EDLC). Polypyrrole is a conducting polymer with promising applications for wearables and for the Internet of Things due to its superior electrical properties. In particular, for the development of electrodes, the low capacitive retention of polypyrrole requires the incorporation of carbonaceous materials as additives. Herein, it is reported the result of systematic studies [1-3] that considered the incorporationof activated carbon, graphene oxide, carbon dots and modified carbon templates by the adequate N-doping process. The effect of the surface modification of activated carbon with polypyrrole was observed from the increase in the energy density of the devices in the order of 175% while incorporating good capacitance retention of the carbon derivative (from values in the order of 60% for pure polypyrrole to near negligible degradation at 1,000 cycles at high current density in hybrid devices). The strategy of mutually doping the carbonaceous substrate before the polymerization shows to be a promising step to reaching outstanding performance in hybrid supercapacitors with the incorporation of nitrogen-based groups on activated carbon returning areal capacitance in the order of 421,4 mF cm-2 and superior capacitance retention (characteristic of carbon derivatives). Piezoelectric polymers, especially poly(vinylidene fluoride) (PVDF), have been receiving considerable interest in the use of prostheses and bone healing, due to their useful special properties, such as non-toxicity, interesting mechanical characteristics, high chemical resistance and remarkable piezoelectricity. In such context, obtaining composites of PVDF and hydroxyapatite (HA), can improve biocompatibility and help bone growth [1]. However, a drawback of using PVDF in medical applications is its hydrophobicity, which compromises cell adhesion and proliferation. In this case, an alternative is the use of pluronic, an amphiphilic copolymer used for the transport of substances and dispersion in physiological solutions, which can promote the formation of self-organized micellar arrangements [2]. Therefore, in the present work, PVDF-Pluronic-127 composites were processed by extrusion, obtaining filaments for 3D printing. The biocomposites were evaluated by scanning electron microscopy (SEM), contact angle analysis and FTIR. Through SEM, it was possible to observe the interaction between the polymers in the blends. The addition of Pluronic made it possible to reduce the contact angle, indicating a hydrophilicity profile of the printed biomaterials. FTIR analysis demonstrate the presence of the polar phase of the PVDF in the biocomposite. Therefore, the composite may have potential properties as innovative devices for biomedical applications.

Solar energy is a rapidly advancing field of renewable energy, with ongoing efforts to enhance efficiency and reduce costs. Perovskite-based solar cells are emerging as a promising option, with recent developments indicating that their efficiency is now comparable to that of traditional silicon cells [1]. The multiferroic material $BiFeO_3$-$PbTiO_3$(BFPT) exhibits ferroelectric polarization, which is responsible for the photovoltaic effect in materials with no center of symmetry, making it a promising candidate for application in solar cells. In this study, BFPT thin films were synthesized using dip coating technique, resulting in a uniform deposition of the material [2-4]. The experimental parameters were optimized to develop a photovoltaic device that showed a response of 3.47 mV/cm².

A large number of studies on (1-x)Pb($Mg_{1/3}Nb_{2/3}$)O_3-xPbTiO_3[(1-x)PMN-xPT] have shown that this system has excellent ferroelectric and piezoelectric properties, mainly for those compositions near the morphotropic phase boundary (MPB) with x=0.30[1]. Several techniques have been designed to grow PMN-PT single crystals in the vicinity of MPB to improve even more the physical properties. Among such techniques, the Bridgman-Stockbarger is certainly the most common one [2]. In order to have a clear understanding and control over the growth parameters to improve the quality of single crystals grown by this route, a prior knowledge of the thermal properties of the precursor oxides is crucial. In this work, the thermal properties of 0.70PMN-0.30PT powder, including thermal conductivity, thermal diffusivity, specific heat capacity, melting and solidification temperatures were investigated. From the thermal properties, the biot and peclet numbers were obtained and thus, compared with theoretical models proposed in the literature to appraise the behavior of the solid-liquid interface during the crystal growth. The structural and segregation coefficients of the as-grown PMN-PT single crystal were characterized and discussed based on the approach used in this work. CsGeI3: a new ferroelectric Rashba semiconductor

Luiz Gustavo Davanse da Silveira[1], José Arruda Freire[1]

[1]Universidade Federal do Paraná (*Física*)

e-mail: luiz.silveira@ufpr.br

Ferroelectric Rashba semiconductors (FERSC) are a new class of multifunctional materials which integrates different subfields: (i) Ferroelectricity (granting the switchability of ferroelectric polarization by an electric field, traditionally exploited in non-volatile memory elements), (ii) Rashba effects (bringing in spin-degrees of freedom and usually exploited in logic semiconducting-based architectures), and (iii) Semiconductor Spintronics (granting the integration with existing semiconductor-based technology). One of the most interesting features of FERSC is the link between spin texture and ferroelectricity, allowing a non-volatile electric control of spin degrees of freedom. This peculiar spin-electric coupling can bring new assets into the field of electrically-controlled semiconductor spintronics. The present study is focused on the ferroelectric perovskite halide CsGeI3. Electronic structure and Rashba-like effects were systematically investigated by relativistic first-principles density functional calculations. The ferroelectric polarization, band structure, densities of states, and spin texture were calculated. The analysis of the results indicates that non-negligible spin-splitting, due to a purely bulk Rashba effect, occurs mostly near the conduction band minimum. The control of the spin-splitting amplitude by changing the ferroelectric polarization was theoretically demonstrated, as well as the complete reversal of the spin texture when the ferroelectric polarization is switched.

Effect of electrodeposition temperature on the crystallinity of Bi2Se3 films grown on different substrates

JOSÉ ROMÃO FRANCA[1], Deise Schafer[1], André Avelino Pasa[2], Cristiani Campos Plá Cid[1]

[1]Universidade Federal de Santa Catarina (*Física*) , [2]Universidade Federal de Santa Catarina

e-mail: joseromaolfisica@gmail.com

Bismuth selenide (Bi2Se3) is a binary compound with attractive properties for application in energy conversion systems, such as thermoelectric and photosensitive devices. In this study, Bi2Se3 thin films were grown by potentiostatic deposition on different substrates (Au, ITO, and Cr) at room temperature (RT) and heated electrolytes to evaluate the temperature effect on properties such as morphology and crystalline structure. As expected, the electrolyte temperature affects the deposition kinetics, accelerating the deposition rate. Differences in the crystalline phase and morphology were also observed with the increase in the temperature of the deposition process. The heating of the electrolyte enabled the formation of more compact films, with mirror-like aspects in the case of Au and Cr substrates. The formation of the pure orthorhombic phase was observed for Au substrates with a decrease in crystallinity with the increase of electrolyte temperature. The film growth on Cr substrates showed the coexistence of orthorhombic and rhombohedral phases, with a predominance of the orthorhombic one. The effect of temperature in this case improves the crystallinity of the deposited layers. The film growth on ITO substrates at RT conditions led to the formation of the rhombohedral phase, with the presence of characteristic peaks of the orthorhombic phase for the heated electrolytes. These observations can provide relevant insights for the adjustment of desirable physical properties of electrodeposited Bi2Se3 layers.

Effect of ionic substitution on the structure andproperties of the $CaTiO_3$ compound

Calcium titanate ($CaTiO_3$), as a incipient ferroelectric, is a attractive material for photovoltaic applications, due to its optical and electrical properties, and for being heavy metals free (Lead Free). However, it does not have polar symmetry, a fact that prevents the bulk photovoltaic effect occurrence, characteristic of non-centrosymmetric materials. To overcome this problem, the iron ion was added to the compound through substitution, obtaining the compound $Ca[Ti, Fe]O_3$. In this work, we study the structure, electrical and magnetic properties of the material aiming to correlate structure-properties. Substitution with different amounts of iron showed significant differences in the structure of the material for photovoltaic applications.

Niobium pentoxide (Nb_2O_5) exhibits considerable potential for use in a wide range of technological applications. Its physical properties (e.g., structural, optical, electrical, etc.) are highly dependent on the synthesis method, chemical composition, and heat treatment conditions, resulting in the formation of different crystalline polymorphs [1, 2]. The present work investigates the influence of heat treatment on the physical properties of Nb_2O_5 nanoparticles. Heat treatments were performed at 300, 500, 800, and 1,000 °C for 1 hour, followed by cooling in ambient air outside of the furnace. Structural analysis was performed by X-ray diffraction (XRD). Morphological characteristics and particle size distribution were evaluated by transmission electron microscopy (TEM) and the optical properties themselves were determined via ultraviolet-visible spectroscopy (UV-Vis), from which band gap values were also determined using Tauc's plot. The results reveal that the crystalline structure of the non-heat-treated sample comprises an amorphous phase of Nb_2O_5 and monoclinic phase (H-Nb_2O_5). With an increase in temperature to 500 °C and 800 °C, a transformation occurs leading to a combination of H-Nb_2O_5 and orthorhombic phase (T-Nb_2O_5). Subsequently, at 1,000 °C, the structure is composed mainly of H-Nb_2O_5. The heat treatments induced changes in the morphological characteristics of the particles, and TEM images demonstrate that particle sintering occurs at 1,000 °C. The range of band gap was found to be around 3.62 eV for non-heat-treated samples and 3.33 eV for those heat treated at 1000°C. These values demonstrate the potential for application in electronic devices, such as photocatalysts.

The recent development of the Internet of Things and wearables requires the integration of electronic devices and batteries/ supercapacitors with requisites of washability, flexibility and long-life cycle. Due to the restrictions of depletion/ periodic substitution of energy storage devices, the development of self-powered systems based on triboelectric nanogenerators applied in electronics introduces advances in wireless communication and biomedical fields[1]. As a consequence, the use of biocompatible and biodegradable materials has proven an outstanding increase due to the interest in wearables and implantable triboelectric nanogenerators. This study reports a novel and simple TENG based on hyaluronic acid and Ecoflex 00-30™ acting as tribopositive and tribonegative pairs respectively, resulting in a simple, low-cost, and easily integrated component for transparent and flexible devices, with output performance of voltage, current, and charge transfer of 398.48 V, 21.88 µA and 85.9 nC respectively. The device also proved to be capable of lighting up commercial LEDs and acting as a sensor of temperature. A calibration curve was evaluated at a fixed range of frequencies and the generated voltage proved an inverse relation with the temperature. An arduino-based system for processing the data was applied in the online identification of the temperature from the generated voltage in the TENG.

In recent years, the freeze-casting process has stood out in the manufacturing of ceramic materials, due to the possibility of creating complex porous structures in a simple and efficient way [1-3]. In this work, α-Al2O3 monoliths were produced using tert-butyl alcohol solvent and parameters were evaluated such as dispersant influence, suspension agitation, and freezing temperature of the process. From the characterization techniques by microtomography, Archimedes'' principle, and electron scanning microscopy, it was possible to observe a total porosity of up to 60%, with the formation of prismatic porosity, with good connectivity between the pores and a decrease in alumina agglomerates when used citric acid dispersant and mechanical agitation of the suspension. The Fourier Transform Infrared Spectroscopy spectra results indicated maintenance of the α-Al2O3 structure and probable improvement in particle dispersion for the system with a freezing temperature of −170°C. In addition, compression tests demonstrated adequate strength in the range of 5 to 9 MPa. As shown, the characterization results corroborate the possible application of the ceramic material as a support for gas separation membranes [1,3].

The pursuit of uncovering innovative materials with exceptional performance has become a pressing matter in the realm of the materials science. Traditional experimental and computational methods often involve substantial investments of both time and monetary resources, and are also constrained by a multitude of factors. This study explores the use of machine learning in materials science [1], specifically in obtaining electrical polarization information from BiFeO3 related materials based on crystallographic data. We demonstrate the effectiveness of machine learning in predicting the electrical polarization of these materials by training a neural network on a dataset of crystal structures and corresponding polarization values. The model achieved high accuracy in predicting the polarization of new materials, even those with complex crystal structures. Our findings highlight the potential of machine learning as a powerful tool in materials science research, enabling researchers to efficiently explore and predict properties of new materials. Intrinsic electrical polarizations were calculated using the Geometrical Polarization Approach" (GPA) [2].

e-mail: rfmuniz@uem.br

Glasses containing sodium silicate co-doped with Nd^{3+} and Yb^{3+} ions were synthesized using the melt-quenching technique. The analysis was performed by varying the doping rate while keeping the concentration of the Nd^{3+} sensitized fixed at 0.2 mol% and the Yb^{3+} activator concentration at 1.0 mol%. The energy transfer mechanisms between Nd^{3+} and Yb^{3+} were analyzed by studying the energy levels involved and the relationship between the emission excitation power and its intensity. The results indicate that the presence of Yb^{2+} is likely in both Nd^{3+}-free and co-doped samples. The energy transfer was confirmed by the low conversion NIR emission spectra of the co-doped samples, which were excited at 808 nm. It appears that the observed mechanisms involve only entail the emission of a single NIR-absorbed photon, which occurs by direct energy transfer between ${}^4F_{3/2}Nd^{2+}$and ${}^2F_{5/2}Yb^{3+}$, with the assistance of the energy difference between these levels. The efficiency of energy transfer increases with the ytterbium content, reaching approximately 90% for the sample with 1 mol% Yb_2O_3, as determined by lifetime analysis. The excitation of trivalent neodymium (808 nm) and ytterbium (975 nm) ions leads to the observed up-conversion photoluminescence. The observed up-conversion emission bands observed are attributed to the 4f-4f transitions of Nd^{3+} and the forbidden 5d-4f transitions of Yb^{2+}. Under excitation at 975 nm, up-conversion of Nd^{3+} is observed, with an almost quadratic dependence of emission intensity on energy. This suggests that two laser photons are involved in the up-conversion process, indicating that the energy transfer occurs through the processes of assisted and cooperative energy transfer.

Perovskites have been pointed out as promising candidates for several technologic areas, especially for photovoltaic applications. In this work, $CaTiO_3$compounds were synthed by using Pechini method. Their structural, optical and electric properties were investigated using X-ray diffraction technique, Rietveld analyses, FullProf and VESTA software. Tilted octahedral oxygen arrangements with similar center of symmetry for positive and negative electric charges are observed forming non polarized Perovskite structures. The origin of the structural observed distortions is directly linked to the strongest chemical bond between the ionic $O_1^{-2}$and Ti^{+4}sites. Direct (2.9 eV) and indirect (3.8 eV) optical band gaps are also observed. Two energy gaps indicate that this compound can absorb energy in two distinct bands, which is interesting for photovoltaic applications.

Glasses doped with Tm3+ ions have been investigated for a practical near infrared phosphor [1]. These phosphors can be used in fiber gyroscopes [2], optical coherence tomography used for biological applications [3]. In the present investigation, we prepared tellurite glasses with 65TeO2-15Li2O-20ZnO and 60TeO2-15Li2O-25ZnO compositions and doped with different concentrations of Tm2O3 (0.5, 1.0 and 2.0 mol%). The purpose of the present work is to report the spectroscopic properties of Tm3+ ions in these tellurite glasses and to have a better understand of the effect of the glassy network on the behavior of Tm3+ ions in these hosts. The samples were synthetized by conventional melt-quenching method. The absorption spectra for Tm3+ were recorded in the UV-VIS and NIR regions. Emission spectra in the visible and near infrared regions were obtained using a continuous argon ion laser and luminescence decay were assessed using nanosecond pulsed laser, both measurements under 476 nm excitation. Tm3+ characteristic emission bands were observed at 650, 805, 1200, 1450 and 1630 nm, corresponding to 3F2,3→3H6, 3H4→ 3H6, 1G4→3H4,3H4 →3F4, 3F4→3H6, respectively. The assigned energy level data of Tm3+ in these glasseswere analyzed and the measured oscillator strengths of the absorption bands, the intensity parameters, Ωλ were calculated by using the Judd-Ofelt theory [4,5]. Using these data, radiative transition probabilities, radiative lifetimes, branching ratios and the integrated absorption cross-section for VIS and NIR transitions were calculated. From these analyses it was possible to indicating slight environmental differences at the Tm3+ ions for the different compositions of tellurite glasses.

Photovoltaic energy conversion has daily intensified the interest in new compounds that present photovoltaic responses combined with low production cost, as well as leveraged the creation of devices on nanometric scales for this purpose. In the quest to circumvent the high production cost and make solar cells more accessible, the use of thin films to compose photovoltaic cells has expanded. Among them, the compound (x)BiFeO3-(1-x)PbTiO3 (BFPT) has been gaining prominence for being a promising multifunctional material with regard to the production of devices for the collection and conversion of energy, as it manifests electrical, magnetic and piezoelectric properties arising from its composition. The BFPT resins manufactured for this work were synthed by chemical route (Pechini method) and deposited on platinum and ITO conductive substrates using the immersion technique. The characterization of the resins and films were performed by rheology and scanning electron microscopy (SEM), in order to quantify their behavior, correlating it with the water control distributed between the resins, to optimize the production process and final cost of the films. The results of the rheological analyzes made it possible to relate the physicochemical properties of the resin with the deposition speed and final thickness of the thin films, by providing information on viscosity, elasticity and behavior over time under the effects of temperature, pressure, shear rate and composition of the resin applied to the material, which allowed a controlled parameterization.

e-mail: SERGIO.LIMA@UNESP.BR

The improvement of energy efficiency of buildings can be achieved by utilizing renewable energy sources, like sunlight[1]. Luminescent Solar Concentrator (LSC) has emerged as a solution for integrating photovoltaic (PV) devices into the structure of buildings. Therefore, the use of LSCs allows the use of solar energy through the coupled LSC-PV device and the harmonization with the local architecture. Luminescent materials can be used for LSCs[2], as they absorb the higher energy incident solar radiation and convert it into a more suitable lower energy radiation for the c-Si PV. Heteroleptic iridium(III) complexes are good candidates for LSCs for gathering the properties an LSC needs. Here, we report the synthesis and photophysical studies of three complexes, $[Ir(C\hat{}N)_2bqdc]$ ($C\hat{}N$=ppy, phq, and bzq), ppy=2-phenylpyridine (Ir-pb), phq=2-phenylquinoline (Ir qb), bzq=benzo[h]quinoline (Ir bb), and bqdc=potassium 2,2''-biquinoline-4,4''-dicarboxylate, that were incorporated into PMMA films varying the doping at 0.1, 0.25, 0.5, 0.75, and 1 wt% via the drop-casting technique on glass substrate. Through UV-Vis spectroscopy, intense absorptions between 300-600 nm were observed, originating from the ^{1,3}LC and ^{1,3}MLCT states. By Photoluminescence a wide emission band was obtained in the deep-red which is in resonance with the maximum optical response of the c-Si PV cell. The 1.0wt% films presented maximum emission at the deep-red, long lifetimes, and good quantum yields: PMMA:Ir(bb): (638 nm; 780 Φ 8.6 %), PMMA:Ir(qb): (650 nm; 806 Φ 1.4 %), and PMMA:Ir(pb): (660 nm; 950 Φ 10.6 %). Herein, we conclude that complex Ir-pb exhibited better properties for future LSC applications since it has the highest Φ, the longest lifetime, and the deepest red emission.

e-mail: rodrigo.santos@indt.org.br

In recent years, piezoelectric materials have motivated interest in energy harvesting due to their ability to convert mechanical energy into electrical energy. In this work, the composite of barium titanate ($BaTiO_3$) and polyvinyl alcohol (PVA) was prepared by the solvent casting method, with a ratio of 1:1 in relation to the amount of solvent used. The diffractogram (XDR) shows that the peak around 20° of the sample refers to the PVA, and the peaks around 22°, 31°, 38°, 45°, 51°, 56°, 65° and 75 ° are compatible with the XRD of $BaTiO_3$, as a result, the nature of both materials prevailed in the produced membrane. The polymer-ceramic interactions were analyzed by infrared spectroscopy (FTIR) where the structural characteristics were observed through the spectrum and the polymer and ceramic bands were identified. The electrical characterization of the sample was performed by complex impedance spectroscopy, from which a superposition of conduction processes associated with the two materials can be observed. The response of the conversion of mechanical energy into electrical energy was made by an electromechanical device which presented a voltage of approximately 40 mV, which can increase or decrease depending directly on the pressure applied to the device. As a result, the piezoelectric response of the synthesized $BaTiO_3$/PVA composite is confirmed.

Production of α-Al2O3 macroporous ceramic materials in Naphthalene-Camphor solvent by the Freeze-Casting technique

Saulo Lucas Pereira da Silva[1], Giovana Magalhães dos Santos[1], Anna Carolina Britto de Faria[1], Camila De Lima Ribeiro[1], Alysson Martins Almeida Silva[1], João Paulo Santiago de Assis Silva[1]

[1]Universidade de Brasília (*Faculdade de Tecnologia*)

e-mail: sauloedgar@hotmail.com

Freeze-Casting is a simple, versatile and very promising process for the manufacture of macroporous ceramic supports for application in gas separation. The technique is based on four steps: slurry preparatio controlled solidification of the slurry, sublimation of the solvent and sintering of the green body. [1,2] The porosity of the sintered material mimics the arrangement of the original solvent crystals, therefore, the shape of the pores is dependent on the nature of the solvent used. [3] This work proposes the study of densification (varying the sintering time), porosity, and mechanical resistance of α-alumina monoliths (α-Al2O3) in three different compositions of naphthalene-camphor solvent - hypoeutectic, eutectic and hypereutectic. The tests showed that, in general, the monoliths presented an average of total porosity of 63.6%, however without clear trends with the change of solvent composition or alteration of the sintering time. Finally, compression tests were performed on the samples to assess the mechanical strength of the material. The normal compressive stresses for each system ranged between 1.53 MPa and 23.56 MPa, and it is possible to observe trends according to the variation in sintering time and material composition.

Production of cubic tungsten carbide films by radiofrequency right angle magnetron sputtering atroom temperature

Munique Eva Paiva de Araujo Monteiro de Barros[1], Noemi Raquel Checca Huaman[2], Elvis Oswaldo López Meza[1], Alexandre Mello[1]

[1]Centro Brasileiro de Pesquisas Físicas (*Física*) , [2]Centro Brasileiro de Pesquisas Físicas (*COMAN*)

e-mail: muniqueeva@cbpf.br

Tungsten carbide is widely used in biomedicine, optics, mechanical, aerospace engineering andrenewable energies [1], due to the different properties such as thermal stability at hightemperatures, good electrical conductivity, high hardness, resistance to oxidation, among others. Of all WC crystalline structures, the cubic system (β-WC) presents greater instability, making itmore difficult to synthesize in thermodynamic equilibrium processes, showing limitedapplications due to this difficulty. In this work, we synthesized thin films of tungsten carbide byright angle magnetron sputtering (RAMS) for the first time. The RAMS system has been widelystudied for the production of thin films of complex crystal structures as hydroxyapatite andsubstituted hydroxyapatite [2]. Our results show a production of crystalline cubic WC prepared atroom temperature. These results are confirmed by grazing incidence X-ray diffraction (GIXRD)and Rietveld refinement, high-resolution transmission electron microscopy (HRTEM), X-rayphotoelectron spectroscopy (XPS), RAMAN spectroscopy and density function theory (DFT).

e-mail: tiagofdr@gmail.com

A triboelectric nanogenerator (TENG) is a system that can convert mechanical energy into electrical energy at a small but steady pace. Self-powered and self-sufficient systems can largely benefit from TENGs, once they can be incorporated onto clothes, inside shoe soles and on car tires. The aim of this work is to prepare a single-electrode TENG capable of generating enough power to charge a capacitor or to power generic integrated circuit components and implantable devices. In the present work, Polyamide 11 and Polydimethylsiloxane (PDMS) were used as the triboelectric pair. A PDMS layer covered an electrode and the relative contact between the polyamide and the PDMS was responsible for generating the charges by contact electrification. The electrodes used were cotton fabrics functionalized with multi-walled carbon nanotubes (MWCNT), pure Buckypapers (BPs) and Buckypapers functionalized with silver nanowires (AgNWs) at different loadings (33.3 and 40 wt. %). Silver nanowires were used to further improve the BP's conductivity.The BPs were prepared by vacuum filtration of a MWCNT suspension in water and Triton X-100 andAgNWs with high aspect ratio were synthed in the laboratory through a polyol process. Thesamples were characterized morphologically by scanning electron microscopy (SEM). Conductivity tests were carried out on the samples of cotton, pure BP and BP functionalizedwith AgNW with and without the PDMS layer. The results showed that the electrical conductivity improved by increasing the AgNW content, as expected. The samples of BP +44wt.% AgNWs achieved the highest electrical conductivity and charge generated at thesurface of 1,4×103 S/cm and 4,33 pC, at room temperature. A higher content of AgNWs andother metallic nanostructures can increase even more these properties, making these materials very promising for engineering applications of low power demand devices.

Properties of Fe and Co doped KNN magnetoelectric ceramics

Eriton Rodrigo Botero[1], Fabio Luis Zabotto[2]

e-mail: EritonBotero@ufgd.edu.br

Multiferroics materials in which the ferroelectric and magnetic properties coexist have been extensively studied in the last two decades for their versatility and possibility of application in an extensive range of electronic devices since their coupled order parameters.
Although mainly the magnetoelectric materials are based on systems with Pb2+ ions in their compositions, such as PZT, becoming a hazardous material since the beginning of its production. Alternatives using other intrinsic ferroelectric systems are the light for environmentally friendly material with similar properties to the regular magnetoelectric materials. In this case, using sodium and potassium niobate, $K_{1-x}Na_xNbO_3$perovskite ceramics becomes a promising solution strategy. In this work were synthed monophase magnetoelectric materials based on doping of KNN ceramics with Fe and Co oxides. The ceramics were densified using three different routes, and the properties were analyzed as a function of the doping and the densification route of the ceramic bodies. The results have shown significant changes in the densification properties in the doped system, mainly due to the site replacement and vacancy formations. All the ceramic bodies present an orthorhombic structure with no traces of secondary phases. The electrical properties show no significant changes in the fundamental properties of KNN, keeping the system with good ferroelectric properties. This work synthes all the properties of this system, looking forward to a new functional and friendly material for electronic applications.

Spectroelectrochemical studies of s-tetrazinederivatives and potential applications.

Dawid Nastula[1], Sandra Pluczyk-Małek[1], Agata Blacha-Grzechnik[1], Pawel Wagner[2]

e-mail: dawid.nastula@polsl.pl

S-tetrazine is a strong electron withdrawing heterocycle containing four nitrogen atoms in a six-membered ring. Many tetrazine derivatives exhibit emissive properties, moreover, their reversible electrochemical reduction often leads to fluorescence quenching. The intense color of s-tetrazine is due to the allowed n-π* transition in the visible range, which is a rare phenomenon. These features, combined with a low molecular weight, are the source of a growing number of scientific publications and potential applications of compounds containing 1,2,4,5-tetrazine[1]. The presented work includes electrochemical and spectroelectrochemical studies of D-A (donor-acceptor) and D-A-D (donor-acceptor-donor) s-terazine derivatives with carbazole electron donating units.

The tested monomers show weak fluorescence. A significant enhancement of the emissive properties was recorded for the soluble products of the electrode reactions. The introduction of a carbazole unit into the molecular structure enables the deposition of a layer by electrochemical oxidation. The obtained stable polymer films based on symmetrical s-tetrazine derivatives undergo electrochemical doping leading to reversible changes in the absorption spectrum and changes in the color of the layer. The results of the measurements indicate the possibility of their use in the production of electrochromic windows.

The use of ferroelectric materials in advanced electronic devices has increased the interest of such systems in high-performance practical applications [1, 2]. Indeed, their current integration in cell phones, ultrasound and medical instruments, sensors, electro-optical devices, as well as energy storage systems, has been possible because of their excellent physical properties with enhanced response in a very wide temperature and frequency interval [2]. In particular, the lead titanate ($PbTiO_3$, PT) ferroelectric system, which has a perovskite structure with tetragonal symmetry (P4*mm* space-group) at room temperature, stands out because of its very high spontaneous polarization, improved piezoelectric coefficient and relatively high Curie temperature [2]. However, because of the lead volatility during synthesis, it is difficult to obtain pure-phase PT system, avoiding the formation of secondary phases [3]. Therefore, for obtaining high quality samples, the synthesis process has to be carefully controlled. In this work, the physical properties have been investigated in PT thin films, obtained from the polymeric precursor’s method. The influence of the synthesis conditions on the structural and vibrational characteristics have been taken into account.

Study of electron transport properties in thin films of Nb_2O_5

Inaiara Leite Rodrigues[1], Cátia Liane Ücker[1], Pedro Lovato Gomes Jardim[1], Mário Lúcio Moreira[1], Sergio da Silva Cava[1]

[1]Universidade Federal de Pelotas

e-mail: inaiaraleite68@gmail.com

Niobium pentoxide (Nb_2O_5) has recently received increasing attention as an electron transport layer (ETL) in flat perovskite solar cells (PSCs) and is considered a possible alternative to replace titanium dioxide (TiO_2). In a typical PSC structure, it is composed of FTO/ETL/perovskite/HTL/metal electrode. The ETL is responsible for transporting the electrons generated by sunlight in the absorber layer to the external circuit of the cell [1]. Nb_2O_5 is a promising candidate as ETL in PSCs. This is partly due to the advances already achieved in energy conversion efficiency (PCE) using Nb_2O_5 as ETL, as demonstrated in [1], with PCE of 18.59%, in [2], with 17.2%, and in [3], with 20.22%. However, it is important to highlight that the synthesis and deposition method of Nb_2O_5 thin film plays a significant role in determining the PCE of PSCs [1]. Therefore, with the aim of obtaining an efficient material, it is necessary to investigate the electron transport properties in Nb_2O_5 thin films. In this sense, this work aims to investigate such properties in thin films manufactured through the Sol-Gel synthesis method, using dip-coating deposition techniques. It is expected to obtain an ideal material by optimizing the optical properties of the films to improve the efficiency of their electronic mobility.

Ceramic materials have advantageous properties for the production of supports used for gas separation. The freeze-casting method has great potential as a scalable manufacturing process for the production of porous ceramics, providing a material of controlled porosity[1-3]. The objective of this work was the production of ceramic monoliths, using camphene as solvent, and the evaluation of the influence of the freezing direction using different molds (copper, technyl, copper-technyl) on the pore morphology. The total porosity of the monoliths varied between 50-70% and this value was confirmed by the μ-CT analysis, it was evaluated that the synthesized monoliths obtained high mechanical resistance where the sample produced in the technil mold obtained the highest values. The SEM images showed that the samples produced in the mixed mold had a change in the perpendicular alignment of the pores in the transition region from copper to technyl [2-3]. In the copper mold, in turn, more aligned structures were observed forming continuous channels, and the technil dendrites did not present continuous alignment. Therefore, the methodology used for the technil mold presented a material with good porosity and ideal alignment of thesepores for application in gas separation.

Supercapacitor auto analyzer: An automated data analysis software for supercapacitor characterization

Miguel Henrique Boratto[1,2], João Victor Morais Lima[1], George G. Malliaras[2], Carlos Frederico de Oliveira Graeff[1]

[1]Universidade Estadual Paulista (*Física e Meteorologia*) , [2]University of Cambridge (*Department of Engineering*)

e-mail: miguelhboratto@gmail.com

High-performance supercapacitors (SCs) with high power, energy, and long-life cycles, are essential for innovating wearable and portable electronics as extensively reported in the literature [1]. The Web of Science shows more than 23,000 papers published since 2018 with the topic 'Supercapacitor', a number that keeps growing, from 732 papers per year in 2012 to an average of 4651 papers per year since 2018. However, the establishment of performance metrics on the reported values should be achieved to reduce inconsistencies in their real performances [2]. For that reason, we developed the Supercapacitors Auto Analyser (SCAA) program for SCs data analysis to support the community to establish performance metrics for SCs devices, with standard terms, equations, and units. The SCAA generates important graphs with the SCs key properties and electrochemical performance such as capacitance, energy, power, coulombic efficiency (CE), equivalent series resistance (ESR), drop potential (Vdrop), cycling stability, and time constant. These results are calculated from common data generated by potentiostat on SCs characterization such as cyclic voltammetry (CV), galvanostatic charge-discharge (GCD), and electrochemical impedance spectroscopy (EIS). With appropriate inputs, the SCAA provides as many as 50 graphs with accurate normalizations by mass, area, or volume in a few minutes. The present work can speed up research on supercapacitors through automation of data analysis, packed in a software shared with the community and in the website www.scaasoftware.com.

The growing demand for electric power has challenged present technologies and motivated researchers to find innovative and affordable solutions to solve this problem [1]. Polymeric solar cells (PSCs) have attracted academic and industrial interest due to their multiple advantages, such as flexibility and semi-transparency. Additionally, they are lightweight and can be produced on large scales at low cost by the industrial roll-to-roll method [2, 3]. In recent years, records of photovoltaic energy conversion efficiencies have been recorded. In order to produce more efficient conjugated polymers, this work aims to explore the synthesis and characterization of polymers with complementary absorption potential for application in a ternary device. The synthesized polymers are relatively simple and obtained from aromatic units of high electronic density: benzodithiophene (BDT) and thiophene (TH), using the Stille coupling reaction. A systematic study was carried out to verify the impact of the different side chains on the chemical and photovoltaic characteristics of these materials. The polymers obtained were characterized by 1H-nuclear magnetic resonance spectroscopy, thermogravimetric analysis, gel permeation chromatography, and UV-Vis spectroscopy. In addition, devices were produced using the synthesized polymers as a donor and PC71BM as an acceptor. For the production of this active layer, the influence of different rotations on the photovoltaic parameters of the devices was evaluated.

Nano-graphene oxide (nGO) is an advantageous and up-and-coming nanomaterial based on its utilization in biomedical, chemical, electrical, optical, energy, and other areas [1]. In addition, its high electrical conductivity is one of the essential parameters for using this nanomaterial in renewable energy and electrical applications. Its electric conductivity is strong-willed by the suppression of dielectric areas of sp^3 carbon atoms linked to oxygen groups separating the planes associated with graphene [2]. Reduced nano-graphene oxide (nGOr) is obtained from the chemical modification of graphene [3]. Considering these essential characteristics of nGOr and Global warming in recent years, this research modified Hummer' s method to obtain nGOr. These nGOr were fully characterized by FTIR, UV Visible, XRD and SEM. FTIR showed chemical groups related to the graphite oxidation process at 3270, 2128, 1705, 1612 and 1032 cm^{-1}. In addition, UV-Vis presented bands at 233 and 300 nm associated to π-π* (graphitized core sp^3hybridization, LUMO→HOMO transition). XRD showed peaks at 25.05° related to graphite oxidation, and at 16.37° and 7.375°, indicating a decrease in layers of 0.541 nm and interplanar distance of 0.7 nm. SEM analysis showed several layers of leaf, resembling a crumpled sheet of paper with wrinkles and folds, due to interactions between oxygenated functional groups. These results demonstrated that the synthesized material presented an excellent quality, which will guide the realization of new syntheses to improve the results and demonstrate several applications for this nanomaterial.

e-mail: thaisabrandao@usp.br

This presentation will focus on organic/inorganic hybrid gels obtained by polycondensation of bis-alkoxysilanes incorporating naphthalene diimide bridges (**NDI**). The resulting **NDI**-based Polysilsesquioxane gels NDI-$[SiO_{1.5}]_2$ were found to exhibit interesting characteristics for many applications, in particular photochromic properties due to the photoproduction of **NDI** anion radicals. To understand the mechanism of photoreduction and its relation to the structure of the 3D network, we explored two different and orthogonal synthetic routes to the targeted polysilsesquioxane gels by studying their influence on the organization of **NDI** bricks within the network.[1,2] A one-step strategy has been developed to simultaneously generate "in situ" the **NDI** bridges and the polysilsesquioxane network (gel **1p**). The two-step strategy conversely required the prior synthesis of a siloxane-substituted **NDI** precursor which was eventually polymerized to form the targeted polysilsesquioxane-based gel material (gel **2p**). Both gels were thoroughly characterized by rheology, XRD/SAXS, spectroelectrochemistry, IR-ATR, Si NMR and impedance measurements. All these measurements suggest that **1p** and **2p** exhibit similar structural, optical and electrical properties.

The need for environmentally friendly devices has driven society to adopt renewable and non-polluting technologies, such as electric vehicles and small appliances powered by efficient and environmentally safe energy storage systems. However, this need increases consumption of raw materials to maintain and develop such technologies. Solid-state batteries and ion-selective membranes emerge as solutions to power devices and extract raw materials, respectively. In this context, the use of ceramic compounds as electrolytes is promising due to their high thermal and electrochemical stability, making them safer than traditional liquid electrolytes [1]. In addition, with its suitable electrochemical properties, ion selector membranes based on ceramic materials are relevant for seawater desalination and for the reuse/extraction of ionic and rare-earths species from batteries and other sources [2]. Those applications require high ionic conductivity, which can be achieved with superionic conductors. In this sense, this research aims to optimize the performance of superionic ceramic electrolytes by using laser-sintering technique. For this propose, $Li_{1.3}Al_{0.3}Ti_{1.7}(PO_4)_3$and $Na_{3.3}Zr_2Si_2PO_{12}$ceramics, with NASICON structure [3], have been prepared by solid-state reaction and sintered by conventional electric furnace for comparison purposes. Preliminary results show ionic conductivity in the range of 0.1-0.9 mS cm-1 at room temperature, which is expected to be improved when sintering using CO_2laser is carried out, due to the microstructure produced by high heating rates.

Theoretical insights on the diffuse phase transition in ferroelectric materials

Hélio Zapparoli Neto[1], Fabricio Macedo de Souza[1], José de los Santos Guerra[1]

[1]Universidade Federal de Uberlândia (*Instituto de Física*)

e-mail: hzappaneto@gmail.com

Ferroelectric materials have been widely investigated over the last decades because of their excellent physical properties, which make them promissory systems for practical applications [1]. In particular, relaxor ferroelectrics with diffuse phase transition have played an important role in electronic devices such as capacitors, sensor, transducers andothers. However, the real mechanism on the diffuse phase transition (DPT) characteristicsremains unclear up today. Therefore, there has been an increasing interest in the scientificcommunity for a careful study of the physical properties of such system in order to betterelucidate the observed intriguing and unsolved phenomena. In fact, although several phenomenological methods have been proposed in the literature to account for the nature of the enhanced diffusivity of the paraelectric-ferroelectric phase transition in such materials [2, 3], the real mechanism still remains a matter of strong controversy. In this work, a macroscopic statistical model, which describe the dielectric response in relaxor systems with diffuse phase transition (DPT) [3], has been used to investigate the dielectric response in the (Pb,La)(Zr,Ti)O_3(PLZT) system, for a composition with relaxor behavior and DPT characteristics. The fitting of the experimental data has been performed via computer simulation using the Monte Carlo (MC) method, and implemented in python programming language.

The study of the variation of luminescent properties with temperature is one promising way to measure temperature in many scientific and technological areas because it allows the determination of the same locally and contactless. Most optical thermometers utilize a ratiometric approach between thermally coupled levels [1-3]. However, such sensors have an inherent limitation of relative thermal sensitivity linked to the maximal energy gap between these levels, which can make them useless for some important applications. This work reports the potential application of $Tm^{3+}/Er^{3+}/Sm^{3+}$tri-doped TeO_2-Li_2O-ZnO (TLZ) glasses as temperature sensors using emitted color and luminescence intensity ratio (LIR) that do not have this limitation. The samples were successfully synthesized by melting quenching technique in an air atmosphere. We have used a fixed concertation of Tm^{3+}(0.2 mol%) and Er^{3+}(0.5 mol%) ions, and three Sm^{3+}concentrations: 0.2, 0.5 and 1.0 mol%. Particularly, we have analyzed the fluorescence intensity ratio (FIR) corresponding to the emissions of these ions, as a function of the temperature. As a result, the highest value obtained to the relative thermal sensitivity was 2.47 $\%K^{-1}$for the FIR related to the emissions at 530 nm and 458 nm, and for the sample doped with 0.5 mol% of Sm3+. In addition, white-light emission was achieved by adjusting the doping concentration of Sm^{3+}ion. Moreover, we obtained CIE color coordinates changing from white, (0.308, 0.317) at 299 K, to yellow, (0.416, 0.514) at 455 K. These results showed that these TLZ glasses are promising platforms for optical temperature sensing, for example, such as safety signal in high-temperature environment.

K-Energy Harvesting: Perovskite, Organic, Hybrid, Quantum Dots, and Dye-Sensitized Solar Cells

Advancements on double-junction silicon-perovskite photovoltaics

Fernando Ely[1]

[1]Centro de Tecnologia da Informação Renato Archer (*COLAB*)

e-mail: fernando.ely@cti.gov.br

New photovoltaic (PV) technologies need to be both high-efficiency and low-cost to reduce the generated energy cost per Watt. To achieve efficiencies above 29% at a reasonable cost, the most advanced and innovative research approach is to combine a silicon (c-Si) sub-cell with a low-cost wide bandgap absorbing material to form a monolithic tandem photovoltaic cell [1]. Tandem cells divide the solar spectrum into parts using multiple absorbing materials which allows them to collect photons more efficiently with reduced thermal effects. Perovskite materials have ideal properties for applications in tandem configurations, including high absorption coefficient, low sub-bandgap absorption and adjustable gap energies between 1.48 and 2.23 eV. Indeed, in April 2023 KAUST University has achieved a new world efficiency record for a silicon-perovskite tandem solar cell with a 33.2% certified efficiency [2]. In this talk, we will overview the most recent achievements on c-Si-perovskite integration covering aspects related to interconnection strategies, perovskite bandgap engineering, processing techniques, optical coupling, stability issues and up-scaling. We will also share preliminary results of the VERTICAL project, a cooperation between CTI and BYD Energy Brasil to develop high-efficiency optimized Si-perovskite tandem PV cells.

This work was supported by the grants #406558/2022-1 (CNPq) and #442553/2019-6 (SisNano/CNPq) and BYD Energy do Brasil (PADIS-Program).

ORGANIC SOLAR CELLS (OSCs): MORPHOLOGY, LIGHT HARVESTING, EXCITON DISSOCIATION ANDENERGY TRANSFER STUDIES.

Lucimara Stolz Roman[1]

[1]Universidade Federal do Paraná (*Física*)

e-mail: romanlucimara@gmail.com

The use of Organic semiconductors for photovoltaic devices presents advantages in processing and on the development of light and flexible devices, using techniques commonly used in the production of large areas, such as spray coating, roll to roll and jet printing ink. The nanostructure matters to efficient organic solar cells (OSCs) due to the compromise a bulk heterojunction (BHJ) formed by electron donor (D) and acceptor (A) components so that excitons created either at the D phase or A phase can efficiently quench at the D/A interface. For a system with optimized charge transport and extraction, the OSC efficiencyis essentially determined by the dissociation of those excitons at the heterojunction. In thiswork, some examples of these studies on the combination of organic materials in thin filmswill be presented in the fabrication of photovoltaic devices obtained by simple mixture in acommon solvent; generated by interfacial synthesi and by mini emulsion technique. Usingsimple mixture, it was possible to study devices from green solvent and in a ternarycomposition in order to rise the photon extracted number and consequently the powerconversion efficiency. The interfacial synthesis allows us to obtain new approach to nanostructure the films, thus obtain new optoelectronics properties and the mini emulsiontechnique allows organic semiconductor nanoparticles synthesis being dispersed in aqueousmedium offering the prospect of overcoming the use of chlorinated, inflammable and toxicsolvents from the manufacturing process of the devices. In addition, the use of commercialorganic solar cells will be presented and discussed in two projects installed at UFPR.

Synthesis and physical properties of low-dimensional0D, 1D, and 2D hybrid organic-inorganic halide perovskites

Jose Antonio Souza[1]

[1]Universidade Federal do ABC (*CCNH*)

e-mail: joseantonio.souza@ufabc.edu.br

Light-harvesting 3D organic-inorganic hybrid halide perovskites have been attracting considerable attention due to their excellent optoelectronic properties. Tuning in their electronic/crystal structures and photoelectric conductivity is at the heart of idealization of new materials, novel functionalities and/or improving the efficiency of optoelectronic devices. The important physical properties include suitable and adjustable band gaps, low exciton binding energy, large optical absorption coefficients, long hole-electron diffusion length leading to efficient charge separation/collection, and high defect tolerance. Compared with the conventional 3D perovskite, the low-dimensional family exhibits better environmental stability and more varied compositions, electronic, and crystal structures. In this talk, we will show some contributions of our research group on synthesis and physical properties of low dimensional 0D, 1D, and 2D organic-inorganic halide perovskites. In particular, we have grown low dimensional perovskites by using a recrystallization process starting from their 3D counterparts. The variation of dimensionality bringing about strong quantum confinement effect leads to change in physical/chemical properties which in turn offer a broad exploration research field for optoelectronic applications including light emitting and solar conversion devices.

Advancing the stability of quantum dot-sensitized solar cells through CuS/carbon composite counter electrodes

Wagner Souza Machado[1], José Agenor Carvalho Júnior[1], Vitor Pereira[1], Marcelo Coelho Batista[1], Marco Antonio Schiavon[1]

[1]Universidade Federal de São João Del Rei (*Departamento de Ciências Naturais*)

e-mail: wagner@ufsj.edu.br

Quantum dot-sensitized solar cells (QDSSCs) are promising candidates among third-generation photovoltaic devices. Semiconductor quantum dots have several characteristics that have attracted much attention recently, including their adjustable bandgap, ease of processing at low temperature and high light absorption. An increase in energy conversion efficiency was reported for different types of QDSSCs in recent years, reaching in the 14% range, making them attractive for large-scale manufacturing. [1] The stability of QDSSCs, however, still remains inadequate for industrial application, especially when they are operated under sunlight and ambient atmosphere, being a barrier to be overcome for large-scale applications. Carbonaceous materials (carbon black, carbon nanotube, etc) have been widely applied as electrodes in solar cells, considerably improving these devices stability.[2] In this work, some of the degradation mechanisms of CuS and CuS/carbon composite counter electrodes (CE) used in QDSSCs were investigated. QDSSCs were prepared using CdS quantum dots and characterized through IxV curves and impedance spectroscopy, during 30 days. It was observed that an adequated control on the deposition and post-deposition parameters (concentration, temperature, time, etc), led to a decrease in some of the main factors responsible for the CE stability, such as an increase in the electrocatalytic activity and better adhesion to the substrate. The CuS/carbon composite CE resulted in a gain in the stability of QDSSCs that was related to the ability of carbonaceous materials to inhibit chemical photocorrosion of the electrocatalyst, which further indicates that CuS/carbon composite CE can become a potential electrode material in the field of solar cells.

e-mail: zilda_ma@hotmail.com

Electrical energy is fundamental for the economy, for science and for sustainable development. Therefore, it is important to seek more sustainable and efficient ways of producing and using electricity, in order to guarantee a safer and cleaner energy future for the next generations. Thus, Perovskite materials have excelled in energy conversion field being considered a potentially cost-effective alternative for the photovoltaic sector [1]. Inorganic perovskites CsPbBr3 have been considered of great interest since they are more thermally stable, due to the replacement of the organic cation by cesium in its structure. Solar cells made from this perovskite composition can be manufactured without the need for an inert atmosphere, presenting itself as a viable alternative when it comes to material greater stability [2]. Additionally, for perovskite solar cells, carbon electrodes are an interesting alternative to the traditional gold electrodes, thus increasing its useful life and reducing the cost of technology [1]. However these devices still suffer from unfavorable charge transfer process and limited light-gathering ability. Intending to boost photovoltaic performance, and evaluate the effect of surface plasmonic resonance, Ag-Au bimetallic nanoparticles (BMN) had been incorporated to devices. The Ag-Au BMN addition provides improvements in optical and morphological properties and improvement in photovoltaic performance, with regard to photocurrent (Jsc) response. In that way they can be used as an effective tool in the improvement of Jsc and consequently, with the possibility of the other parameters optimization, in the efficiency of photovoltaic devices.

e-mail: roger.hiorns@univ-pau.fr

Main-chain fullerene-based polymers are still relatively rare. However, because they combine the properties of fullerene, such as exceptional electron acceptance capability and semiconductivity, with those of polymers such as good solubility and excellent film-forming characteristics, they are gaining particular interest for their use as interlayers in photovoltaics and organic electronics. They exhibit many of the properties of fullerenes, combined with the ability to be formed as a regular thin film. For examples, recent work has demonstrated their use as interlayers in perovskite solar cells to give efficiencies around 23% and good stabilities[1], and that they might find use in ammonia sensors [2]. The methodology used to make these polymers can impact extremely heavily on its final physico-chemical properties. Therefore in this work, by way of introduction, we review the different known methods of preparing main-chain poly(fullerene)s and how those methods can modify the polymer's behaviour in application [3-6]. We further look to new methods for reacting with the chain-ends of these materials to expand their properties, especially by combining them with poly(ethylene glycol) to give amphiphilic materials. It is expected that these new materials might be of interest for 'green' processing of interlayers and drug delivery systems.

CsPbBr3 QDs Changing the Morphology and Structureof MAPbI3 Films for Perovskite Solar Cells

Helder Moreira Braga[1], Andre Sarto Polo[2]

[1]Universidade Federal do ABC (*PPG Nanociências e Materiais Avançados*) , [2]Universidade Federal do ABC

e-mail: heldermb2@Gmail.com

Perovskite solar cells (PSCs) are currently one of the most promising semiconductor materials for solar energy conversion, combining high efficiency, ease of manufacture, and economy. On the other hand, halide Perovskite Quantum Dots (PQDs) present intrinsic properties that may be interesting for photovoltaic applications, low defect density, compatibility with large-scale de-position techniques, and adjustable bandgap. In addition, all-inorganic perovskite has been shown to have higher stability than organic-inorganic hybrid perovskite (PK) materials under ambient conditions. An effective strategy to promote the long-term stability of PSCs has been coating moisture-resistant layers on the surface of the PK. Thus, PQDs are a promising candidate for interface engineering in PSCs due to their stability and adjustable gap position. Therefore, in this work, we investigated the influence of CsPbBr3 PQDs on the PSCs layer' s morphological, optical, and structural properties. The incorporation of PQDs in PK films was achieved by depositing its suspension onto the substrate surface and forming the MAPbI3 PK film by the sequential deposition method. Another approach was to deposit PbI2 followed by PQDs suspension and, finally, MAI; resulting in PK film with PQDs. Preliminary results of scanning electron microscopy show that the presence of PQDs leads to the formation of different morphology depending on the deposition procedure employed. Depositing PQDs before the PK formation resulted in films with nanocrystals with well-defined cube-shaped like, while the deposition of PQDs between PbI2 and MAI does not change the morphology of PK films. In addition, preliminary XRD results indicate that with the introduction of PQDs, the perovskite structure is kept. Further experiments using these films in PSCs are in progress.

Multimodal Spectroscopic Characterization ofPerovskites for Photovoltaic Applications

Francis Ndi[1], Igor Alessandro Silva Carvalho[2], Felipe Cabral[3]

[1]HORIBA Scientific, [2]Horiba Instruments Brasil (*Scientific*) , [3]Horiba Instruments Brasil

e-mail: francis.ndi@horiba.com

Research in the last two decades has led to significant advances in the performance for Perovskite materials for photovoltaic (PV) applications [1]. Along with their significant advantages, PV Perovskites also tend to have strong vulnerabilities to environmental conditions, and are easily degraded from exposure to water, light, temperature and oxygen leading to poor long-term stability [2].

Some of the work being done today include designing Perovskite materials to have optimal optoelectronic properties for PV, uniform deposition of thin films, and proper protection or passivation of the resultant solar cells to enhance their long-term stability and performance. This work requires a variety of spectroscopic characterization tools which have historically been separate pieces of equipment. In this presentation, we show a novel multimodal spectroscopic characterization platform that combines a variety of spectroscopic modalities including Photoluminescence (PL), Raman, TRPL Electroluminescence for characterization PV Perovskites.

Figure 1: (a) Steady state Photoluminescence map of solar cells showing uniformity. Insert is a high spatial resolution map of a defect. (b) Time resolved Photoluminescence measurement of carrier lifetime away from, at the edge of, and within the defect shown in the insert in figure (a)

With this new instrumentation design and configuration, we demonstrate a vertically integrated platform for determination of several of the performance indicators of Perovskites for PV application. From basic material properties such as carrier dynamics all the way to PV efficiency in the resulting solar cells. Furthermore, these modalities can be readily added to any standard optical microscope.

Photoinduced Frenkel pair defect lead phase-segregation in halide perovskite alloys

FERNANDO PEREIRA SABINO[1], Gustavo Dalpian[1], Alex Zunger[2]

[1]Universidade Federal do ABC (*Centro de Ciências Naturais e Humanas*) , [2]University of Colorado Boulder (*Renewable and Sustainable Energy Institute*)

e-mail: fernandopsabino@yahoo.com.br

Alloys of halide perovskites can be very different from other tetrahedral semiconductors. III-V or II-VI semiconductors generally have good miscibility if the atomic sizes are similar, andtend to phase-separate below a given miscibility temperature if their atomic sizes are sufficiently mismatched. Alloying two HPs with different halogen ions X and X’ can lead to their complete miscibility in the dark, and phase-segregate into their parent compounds under brief light exposure. This effect has been observed in hybrid and inorganic alloys of HP. Thermodynamic properties or intrinsic defects were invoked to explain the phase segregation under light or remixing under dark in alloys of HP, however, these models do not bring a complete explanation for the process. In this work, we clarify via first principles defect calculations that a Frenkel like pair (FP) defect complex is the main agent for phase segregation. This process can be described as a sequence of steps: First, the photogenerated holes, delocalized at the valence band, can lower their energy when I dislodge from its lattice site, leaving behind an iodine vacancy (V_I) and forming a FP complex $(V_I+I_i)^{2+}$. The associated FP tends to form on alloys with an intermediate concentration of I and Br, and in a I-rich local chemical environment. Second, in the same intermediate alloy concentration, the FP tends to dissociate into $V_I^{1+}+I_i^{1+}$. Third, the migration of I into $V_I$is faster and can produce I-rich and I-depleted regions. The phase segregation process stops when the local chemical environment of alloys becomes like the separated parents’ composition, where the FP does not form. In the dark and under thermal annealing, the excess of holes is suppressed, and the entropy increases in the halide perovskite killing the photoinduced $V_I$and $I_i$and returning to the original form.

In recent years, hybrid perovskites have been developed with an organic and polar structure (with a permanent electric dipole) CH3NH3. In these materials, the inorganic part is a lead halide (PbI3, PbBr3 or PbCl3). The photovoltaic performance of these perovskites is due to dipole fluctuations of the organic part CH3NH3. This research shows that it is possible to improve the stability of perovskite MAPbI3 by properly incorporating salophen atoms into its matrix; thus, the results indicate that perovskite MAPbI3/salophen has a better stability. This organic ligand can coordinate with the Pb (II) metal centre in tridentate or tetradentate form through a combination of any nitrogen or oxygen donor atom. It can also be in the mono-deprotonated or neutral form. Consequently, it is sterically ideal for establishing tetryl bonding interactions with electron-rich nitrogen our bromide atoms. The improvement is linked to the structural transition from the tetragonal to the cubic phase, a more stable structure as shown by the X-ray diffraction (XRD) results. In this research, we performed the preparation of the perovskite precursor solution, the deposition of films by spin-coating, and characterisation to study the structure and photophysical behaviour of MAPbI3/salophen. The perovskites were deposited on transparent conductive fluorine-doped tin oxide (FTO) substrates, the films were characterised by X-ray diffraction (XRD), UV-vis absorption, and also emission (PL) and excitation (PLE) photoluminescence. Perovskite- based solar cell devices containing salophen with 18.22% efficiency, given by the PCE index(Power Conversion Efficiency). The research also reinforces the study of the stability of theoptical and electronic properties of this perovskite; in order to understand the mechanismresponsible for the degradation of this material, this point is essential for us to build materials with better stability and photovoltaic efficiency.

Synthesis and Characterization of Stable 2D Perovskite Incorporating a Thieno-Pyrrole-Containing Ligand and 2D/3D Interface Engineering

e-mail: a.bonadio@ufabc.edu.br

Two-dimensional (2D) perovskite materials have been attracting increasing attention due to their higher stability in ambient conditions compared to 3D perovskite materials, resulting in increased stability of perovskite optoelectronic devices. Furthermore, chemical functionalization of organic spacers is an effective approach for tuning the 2D Ruddlesden-Popper (RP) electronic properties. Here, we report the synthesis and characterization of a new 2D layered perovskite incorporating a π-conjugated thieno-pyrrole ligand $(TP\text{-}TEA)_2PbI_4$. Structural and morphological analysis confirm the formation of microplatelets 2D RP perovskites with triclinic symmetry. The hydrophobic organic spacer layer provides natural protective barrier for transport of ions and moisture, offering significantly improvedlong-term stability for these 2D perovskites. We have systematically investigated the morphological, structural, optical, and electronic properties of these 2D perovskite separately and placed them on the top of 3D films, forming 2D/3D heterostructures for studyin perovskite solar cells. The absorption of 2D/3D perovskite films showed similar bandgapand absorption profiles in comparison with that of control 3D perovskite films. Time- resolved photoluminescence shows that the isolated new 2D RP perovskite has longer charge carrier lifetime when compared with PEA and TEA-based perovskites. In addition, the recombination rates for TiO_2/perovskite are faster when using the new ligand in 2D/3Dheterostructure, indicating more efficient interface charge transfer at the hole-transport layer/perovskite interface. These results are discussed based on the passivation effect brought by the new ligand which increased the overall stability of the perovskite layer anddecreased the nonradiative recombination rates.

Synthesis of perovskite thin films from sputtered lead iodide

José Maria Clemente da Silva Filho[1], Francisco das Chagas Marques[1]

[1]Universidade Estadual de Campinas (*Instituto de Física Gleb Wataghin*)

e-mail: zemarjmc@ifi.unicamp.br

Synthesis of high-quality organolead trihalide perovskite ($CH_3NH_3PbI_3$) has been the subject of intense investigation due to their attractive optical and electronic properties, e.g., direct bandgap, high absorption coefficient, and ambipolar charge transport. The main route used to synthesize $CH_3NH_3PbI_3$ thin films for highly efficient solar cells is based on spin-coating deposition. This approach has produced solar cells with power conversion efficiencies higher than 25%. In this work, Lead Iodide (PbI_2) thin films, were deposited through rf- sputtering and then successfully converted into perovskite films using a two-step process. The sputtered PbI_2 films were evenly deposited on large areas and on different substrates. The as-deposited PbI_2 thin films were converted into $CH_3NH_3PbI_3$ by immersion in a methylammonium iodide (CH_3NH_3I) solution. By this approach, we synthesized $CH_3NH_3PbI_3$ thin films with good optical and structural properties. The perovskite films presented an optical bandgap of 1.5 eV and crystalline structure in accordance with the reported in literature. This new method is fully compatible with large-scale manufacturing. Besides, it has the potential to open a way toward reproducible and high-efficiency $CH_3NH_3PbI_3$ solar cells.

Acknowledgments

Thermal degradation kinetics of halide perovskites with mixed organic cations

Fernando Brondani Minussi[1], Rogério Marcos da Silva Jr.[1], Eudes Borges Araújo[1]

[1]Universidade Estadual Paulista (*Departamento de Física e Química*)

e-mail: f.minussi@unesp.br

Halide perovskites are a group of materials extensively studied in the last decade due to their versatility of compositions and properties that allow wide optoelectronic applications. This potential, however, is limited by the low stability of these materials and their devices. Many degradation routes are known, among which thermal degradation is of particular relevance in compositions containing organic cations. Although abundant literature has been devoted to this topic, little attention has been given to the effect of different cations onthe kinetics of degradation in these halide perovskites. In the present work, we studied the thermal degradation kinetics of perovskites of compositions MAPbI3, FA0.10MA0.90PbI3, GA0.10MA0.90PbI3 and GA0.05FA0.05MA0.90PbI3, where MA, FA and GA are respectively the organic cations methylammonium, formamidium and guanidinium. The kinetic constants obtained by changing X-ray diffraction patterns as a function of time in samples subjected to temperatures between 150 and 200°C reveal that the compositions FA0.10MA0.90PbI3 e GA0.05FA0.05MA0.90PbI3 show slower thermal degradation than MAPbI3, where the GA0.05FA0.05MA0.90PbI3 composition appears to be the most stable. However, contrary to general expectations, the composition GA0.10MA0.90PbI3 has higher kinetic constants than MAPbI3. Furthermore, the composition GA0.10MA0.90PbI3 shows a degradation route different from the others. This work highlights the importance of the rational choice of the different organic cations to be used in a halide perovskite composition for a given application of interest.

Ti_3C_2 MXene as efficient additive for high-performance inverted perovskite solar cells

Hugo Gajardoni de Lemos[1], Jéssica Helisa Hautrive Rossato[1], João Pedro Breveglieri da Silva[1], Gabriel Dias Trevisan[2], Victor Piovesane Silva[2], Carlos Frederico de Oliveira Graeff[2]

e-mail: hugogajardoni@hotmail.com

Inverted perovskite solar cells (IPSCs) have drawn attention due to their low-temperature fabrication process and negligible hysteresis. [1]. Even though showing several advantages, these inverted (p-i-n) structures still lack of desirable high performance and long-term stability. MXenes, an emerging class of two-dimensional (2D) transition metal carbides and nitrides, has been studied due to their unique properties such as high electrical conductivity, high transmittance and high hydrophilicity [2]. In this work, high performance IPSCs were obtained by inserting Ti_3C_2MXene as passivation agent in the perovskite layer. Low concentration of $Ti_3C_2T_x$with respect to $Cs_{0.17}FA_{0.83}Pb(I_{0.83}Br_{0.17})_3$PVK resulted in increase of $J_{sc}$and FF. Moreover, V_{oc}improved to 1.12 ± 0.01 against only 1.08 ± 0.03 V of the pristine devices. Then, the improvement of the functional parameters of PSCs contributed to substantially increase PCE to 21.27 ± 0.66 % when compared to the pristine devices (18.80 ± 1.43 %). Photo-CELIV characterization showed improved charge mobility and higher density of extracted electrons of PSCs after addition of MXenes. Fitting of TPV curves showed longer charge recombination time of the devices containing MXenes. These results were accompanied by a decrease of the charge transfer resistance and an enhanced charge recombination resistance, as shown by EIS. These features can be mainly attributed to the high electrical conductivity of MXene, which works as an effective charge transfer path and prevents their recombination at the perovskite/ETL interface. This premise was confirmed by the reduced number of calculated traps of PVK-Ti_3C_2, indicating a defect passivation by the MXene.

Ab-initio phase diagram of CsPbBr3

Lucas Martin Farigliano[1], Fabio Negreiros Ribeiro[2], Gustavo Martini Dalpian[1]

[1]Instituto de Física da Universidade de São Paulo, [2]INFIQC, CONICET, Departamento de Química Teórica y Computacional, Facultad de Ciencias Químicas, Universidad Nacional de Córdoba

e-mail: lfarigliano@unc.edu.ar

Lead halide perovskites are promising for use in solar cells and optoelectronic devices, but stability concerns limit their possible applications. Understanding their atomic structure is important for the optimization of performance in photovoltaics, radiation detection and thermoelectric systems. Cesium lead halides (CsPbX3) are particularly promising due to their stability at high temperatures and desirable properties such as band gaps. However,CsPbX3 are temperature-sensitive and exhibits different phases at different temperatures. This theoretical study aimed to analyze the variation of the structure of CsPbBr3 perovskiteas a function of temperature. To achieve this, Ab Initio Molecular Dynamics were performedin an NPT ensemble with a completely flexible cell, keeping the pressure and temperature constant. Multiple temperature values between 150 and 500 K were considered, while the pressure was kept at zero in all simulations. The calculations were performed at the DFT level using the CP2K software. The variation of the average volume of the CsPbBr3 unit cell at different temperatures was measured and the corresponding average structures were determined. In addition, the behavior of the structural parameters of the cells in each simulation was analyzed, allowing to detect that the average structure is not present all the times during the simulation, but the system shows different geometries at a given temperature. The frequency with which these different geometries were observed in the simulations could be calculated. Angle tilt and band gap analyses were also carried out. This study has allowed us to conclude that the geometry of the CsPbBr3 perovskite undergoes fluctuations at specific temperatures. In addition, by analyzing the tilt angle of PbBr6, the mechanisms by which phase changes occur in the perovskite structure as a function of temperature have been elucidated. This work has been funded by FAPESP and by CNPq, through the Materials Informatics INCT.

γ-CsPbI3 nanoparticles: light-induced self-assembly and optical properties

Daniel Gau[1], Isabel Galain[2,3], Ivana Aguiar[4], Ricardo E. Marotti[1]

e-mail: dgau@fing.edu.uy

Metallic halide perovskites (MHPs) have excellent optical properties, which has led to awake the interest of the scientific community, and their implementation in a variety of optoelectronic devices, such as solar cells, light-emitting diodes, lasers, etc. However, a deep understanding of the fundamental properties of this kind of materials is still needed. Inthis work, we synthed γ-CsPbI3 nanoparticles capped with (3-Aminopropyl)triethoxysilan (APTES) and oleylamine by the hot injection method. The nanoparticles were cubic of 32 nmin . We irradiated the nanoparticles with a solar simulator, and we could observe that thatthe nanoparticles self-assembled into nanorods. Moreover, we studied the optical properties obtained from the photoluminiscence spectra at low temperature. Our results showed that the self-assembly process does not affect considerably the interaction of excitons and phonons, but it could affect negatively the crystalline network quality. Besides, we observed that the detachment by light of the capping agent could be responsible for the self-assembly. The fundamental processes that are responsible for this effect are still unknown, and further studies will be focused on the study of the factors that affect the final characteristics of the assembled nanorods.

The great challenge for photovoltaics is to obtain high efficiency and low-cost devices.Nanomaterials allow the improvement of electrical conductivity and light absorption.Graphene oxide (GO),with high surface/volume ratio,great mechanical and chemical stability and high electric and thermal conductivity[1] is promising nanomaterial in this field.Otherwise,Poly(3,4-ethylenedioxythiophene):poly(styrenesulfonate)(PEDOT:PSS),as a transparent and stable polymer,with high conductivity and ease of processing,is widely used in organic solar cells [2].So,a combination between PEDOT:PSS and GO can improve,concurrently,electrical conductivity and mechanical properties of biopolymer membranes.Biopolymers are interesting options for photovoltaic substrates,because of low-cost production,versatility and low environmental impact.Xanthan is a biopolymer already used in electronic devices[3] and,with the addition of plasticizers and crosslinkerrs,forms transparent and flexible substrates.The purpose of this study was prepare xanthan biopolymeric substrates modified with GO and PEDOT:PSS to obtain optimized electrical and optical properties for organic photovoltaic devices.For the preparation of biopolymeric membranes,xanthan was dissolved in deionized water,ethylene glycol was used as a plasticizer,and glutaraldehyde was used as a crosslinker.GO was added in a solution with different concentrations of it and PEDOT:PSS was added during membrane synthesis or after,by spin coating deposition.Morphological,electrical and optical properties have been studied and correlated with the preparation methods evaluated in this study.Preliminary results indicated a increase in the electrical conductivity and stability overtime for membranes modified withGO or PEDOT:PSS.Acknowledgements:CAPES,FAPERJ.References:[1] J.E.D Vieira et al.Revista Eletrônica de Materiais e Processos,v.11,n.2,p.54-57,2016 [2] S. Abstract: The increase in energy demand, environmental problems and the possible scarcity of non-renewable energy sources are some of humanity''s recent concerns. In this scenario, scientists are looking for ways to develop technologies for energy production from renewable sources and with low environmental impact. Third-generation solar cells are a possible solution for sustainable and low-cost energy generation [1]. However, one of the challenges of this generation is to improve stability and reduce energy losses. Carbon-based electrodes have been widely studied, seeking to increase the lifetime and energy conversion efficiency of 3rd generation cells, due to their electrical and mechanical properties, stability, low cost and high surface area [2]. In this work, carbon electrodes were prepared from carbon-based pastes (Multi-Walled Carbon Nanotube (MWCNT) and Carbon Black) of different compositions, in order to investigate their electrical properties. The electrodes were characterized by Cyclic Voltammetry and Polarization Curves techniques. Electrical conductivities were obtained for the different compositions of the electrodes used. Cyclic voltammetry allowed investigating the stability of the electrodes as a function of concentration, allowing an optimization of the concentrations of the paste components. It was concluded that the carbon paste based on MWCNT, presented better conductivity, being more suitable for application in solar cells. In the future, we seek to understand the effect of the morphology of these electrodes (roughness, surface area, thickness) applicated to 3rd generation solar cells.

e-mail: fernando.takashi@ufabc.edu.br

Hybrid perovskite-based solar cells have been widely studied throughout thelast decade since it allies the inorganic high conductivity and performance to theorganic processabilityand low cost. The current hindrance to the large-scaleproduction of this kind of solar cell isits stability facing degradation processes toadjacent layers and external factors, mainly to humidity. P-type metal oxidesemiconductors are promising candidates as a hole transport material ininverted perovskite solar cells, due to their enhanced optoelectronic properties:improved hole mobility, suitable bandgaps and high transparency, and fittingenergy levels with the active layer [1]. These materials also provide chemicalstability and a humidity barrier to the active layer. The present study involvesthe experimental characterization of copper delafossite thin films as analternative to the hole transport material conventionally used. Copper aluminatedelafossite thin films have been deposited using reactive RF-sputtering andcharacterized by X-ray diffraction, Raman Spectroscopy, X-ray PhotoelectronSpectroscopy, Four-probe Resistivity measurement, and UV-Vis Spectroscopy. Scanning Electron Microscopy, Contact Angle measurements and Ellipsometrywere also performed to study the deposition dynamics and the thin film surface.

e-mail: m.marafiga7@gmail.com

In the past decade, lead halide perovskites have garnered significant attention due to their impressive photoluminescent properties and photoconversion efficiencies. However, their application has been hindered by their instability towards heat and moisture, which results in the leaching of lead into the environment. In recent years, full-inorganic lead-free perovskites have emerged as a promising alternative, with tin being the most common substitute. However, the oxidation of Sn^{2+}poses a significant challenge, making its application difficult [1]. To overcome this challenge, researchers have turned to antimony halide perovskites, which possess promising luminescent properties [2,3]. In this work we synthesized antimony halide perovskites $Cs_3Sb_2X_9$(X = Cl, I) through a simple precipitation process [3]; in this method, $SbX_3$is dissolved in acid media and adding the corresponding cesium halide to the solution achieves instantaneous perovskite precipitation. To optimize synthetic conditions and obtain a higher yield, we employed a three-factorial design of experiments (2^k, k =3), with temperature, solvent, and precursor concentration being the factors studied. To our knowledge, there are few studies regarding synthetic conditions to these materials so our work may be of great value to the field.

Degradation Study in Organic-Inorganic Perovskite Halides Thin Films on Different Substrates

Guilherme Aparecido da Silva Felicio[1], Eralci Moreira Therézio[1], Romildo Jerônimo Ramos[1]

[1]Universidade Federal de Mato Grosso (*Instituto de Física*)

e-mail: guilherme@fisica.ufmt.br

In this work, perovskite thin films of organic-inorganic multication lead halides (HOIP) were studied to understand how the degradation process affects the optoelectronic properties of the films on different substrates. Perovskite films were synthesised using the one-step method, which consists of dissolving the reagents in well-defined stoichiometric amounts utilising a combination of solvents that produces a precursor solution. Then, the solution was deposited on the substrates by the centrifugation technique and, before the end of the centrifugation process, an antisolvent was dripped. Then, the substrate containing the precursor film was placed on a heated plate at a temperature of 120°C for 30 min for perovskite formation to occur. Glass substrates, fluorine-doped tin oxide (FTO), indium tin oxide (ITO) and poly-3,4-ethylene dioxythiophene:poly(styrene sulfonate) (PEDOT: PSS) were used for the deposition. Characterize the films, traditional spectroscopy techniques were used to characterize materials with optical properties, such as UV-Vis absorption and Photoluminescence (PL), and X-Ray Diffraction (XRD) techniques will be used to describe the film structures. These techniques have allowed a systematic investigation of the optical properties of films and the monitoring of how they change as the material degrades due to exposure to heat and humidity. For studies of the degradation process, the degradation protocol was carried out over 30 days, in which day 1 was the specific day in which the films were synthesised and during the first five days the optical characterization measurements were taken. Once a day at the same time, and for the remaining 30 days, optical measurements were retaken on days 10, 20 and 30. As for the structural characterisation measure, a second batch of films was synthesised, which measurements were taken on the 1st, 5th, 10th, 20th and 30th.

Nowadays, perovskite solar cells (PSC) draw great interest in the field of energy harvesting due to rapid increase in the efficiency, reaching above 25%, and as a substitute for the silicon solar cells in the near future [1]. Nevertheless, not the only, but one of the problems of these devices is the stability, addressed to different causes [1]. Usually, those cells are made using the perovskite layer as an absorb material, between selective transport layers, being called p-i-n for the case that a hole transport layer (HTL) comes beforehand the perovskite layer. The correct selection of materials for selective layers is essential for good performance of the device. Thus, the use of metal oxide layers has been investigated in order to improve the stability and make it commercially viable. In this way, the cobalt oxide (CoO) is presented as a potential option [2]. Therefore, this work explored the deposition of CoO by reactive sputtering and its use as a HTL in the PSC. Sputtering is a well-known method to deposit metal oxides, and tuning the deposition parameters allows the change of the film properties [3], which can lead to desirable conditions to apply the CoO as HTL in the devices. The devices manufactured with the CoO as HTL, reached 6 % of efficiency. Although, the efficiency may be beneath the expected, this gives insights in ways to improve the layer deposition and its whole in the device, concerning the comprehension of the causes that limit the performance of the cells.

This work aimed to study the parameters for obtaining PMMA nanofibers to use as the shell of a coaxial nanofiber structure. These structures will be used as the active layer of a BHJ solar cell, the core is a conductive polymer, and the shell is PMMA. The first parameter studied was the type of solvent with acetone, chlorobenzene, and dimethylformamide. The polymer has good solubility in the three solvents, and acetone was chosen because it has a lower boiling temperature value. The second parameter was the concentration of the PMMA solution in acetone, and concentrations of 5%, 7.5%, and 10.0% by mass were tested. For this study, a viscosimetry analysis of the solution was applied. The samples used for electrospinning were those with 5% and 7.5% concentrations since the 10.0% solution presented a very high viscosity value concerning the other solutions. The studied electrospinning parameters were the distance between the needle and the collector, the application of the electric field, and the pump flow. The distance was varied by 10.0 cm, 12.5 cm, and 15.0 cm. The applied electric field values were 15 KV, 17 KV, and 20 KV. The pump''s flow changed to 0.5 ml/h, 1.0 ml/h, and 2.0 ml/h. The most promising set of samples, which resulted in the best PMMA nanofibers, without beads and in the suitable thickness for the application, was the one with the parameters of 5% concentration by mass, applied voltage of 20 KV, flow rate of 0.5 ml/h and distance between needle and collector in values of 7.5 cm, 10.0 cm, and 12.5 cm.Acknowledgments:Coordenação de Aperfeiçoamento de Pessoal de Nível Superior, CAPES Foundation

DEVELOPMENT OF SOLAR CONCENTRATOR BASEDON LUMINESCENT NANOCRYSTALS

Luminescent Solar Concentrators (LSC) were introduced nearly four decades ago as a potential complement to silicon solar cells and are considered a powerful photonic platform.1 They consist of a semitransparent glass or polymer waveguide doped or coated with highly emissive luminophores, which after absorbing sunlight re-emit photons at longer wavelengths. Total internal reflection guides the luminescence to the edges of the waveguide, where it is converted into electricity by photovoltaic cells coupled to the concentrators. This form of light concentration is passive and inexpensive, without the need to using expensive and bulky equipment. In addition, the inherent ability to indirectly illuminate connected photovoltaic cells gives the LSC device the added benefit of being less sensitive to shading than conventional solar cells.2 In this work, the development of a solar concentrator at based on Dimethylpolysiloxane (PDMS) polymer, doped with quaternary quantum dots (QDs) of CuZnInS/ZnS, coupled to a $CuInS_2$solar cell was described. Due to the suppressed reabsorption and the high emission efficiencies of the quantum dots synthed, an efficiency increase in the solar cells was achieved compared to the ones where the solar concentrator was not used. In this way, it was possible to demonstrate the use of stable and ecologically correct QDs to produce large-area LSCs, capable of increasing the optical efficiencies of solar cells.

$BA_2MA_{n-1}Pb_nI_{3n+1}$ are promising 2D Metal Halide Perovskites (MHPs) that have been largely investigated in the last few years and are emerging as an alternative to their former 3D $MAPbI_3$counterpart because of their attractive structural versatility and tunability of optical properties for solar cells. This 2D MHPs are based on methylammonium ($MA = CH_3NH_3^+$) cation and the hydrophobic butylammonium ($BA = CH_3(CH2)_3NH_3^+$) organic spacer, which promotes more moisture stability. A theoretical approach capable of describing a correlation between local distortion and optoelectronic properties, such as gap energy and absorption coefficient, is challenging. Here, we analyze via ***ab initio***density functional theory how the structural and electronic properties of the Pb_nI_{3n+1}octahedrons behave under partially canceled dipole moments through the NH_3^+terminal cations from MA and BA [1] - no excitonic properties are included. It is well-known that at room temperature, the MA cation begins to rotate inside the cage. However, our discussions focus on dipole moment orientation at 0 K as a vital step to advance the knowledge about 2D MHPs. For n = 1, 2, 3, 4, and 5 layers, employing a relativistic treatment with the DFT-1/2 quasiparticle and spin-orbit coupling (SOC) corrections, our results show that the octahedrons surface via no dipole moment cancellation induces the best data calculated and is in good agreement with experimental gap energies. In the opposite scenario, the dipole moment cancellation promotes the closing of the gap energies and shows an electron depletion mechanism. Furthermore, the interaction octahedron-MA yields high metal off-centering associated with strong SOC which resulted in bulk Rashba splitting. Finally, only the no dipole moment cancellation scenario converges to the bulk absorption coefficient and can keep the performance of 2D perovskites comparable to their 3D counterparts.

e-mail: everton@fisica.ufmt.br

In this work, the films were deposited using the spin-coating technique based on the variation of the active layer, which may be the Poly- (3-hexylthiophene) polymer (P3HT) or the P3HT:PCBM blend, and the buffer layer, which may be the PEDOT: PSS blend or the PEDOT: PSS: GO blend, and after deposition, optical and morphological characterizations were performed to study the photophysical properties and the interaction between the different deposited layers. The films were deposited on a glass substrate with an Indium tin oxide (ITO) layer. Afterwards, optical characterizations were performed using Ultraviolet-Visible Absorption Spectroscopy (UV-Vis), Photoluminescence Spectroscopy (PL), Photoluminescence Excitation Spectroscopy (PLE), and Emission Ellipsometry (EE), as well as morphological characterization using Atomic Force Microscopy (AFM), which was also used to measure the thickness of the films. As a standard deposition method, the rotation speed was set at 3000 RPM for the buffer layer and 2400 RPM for the active layer, thus comparing the variations in optical measurements according to the films so that the thicknesses are similar. It was noted that GO has excellent influences on optical measurements and the interaction it presents with PCBM. Both gave its quenching effect, as observed in the PL measurement and made the transfer of energy more uniform concerning the film ITO/PEDOT: PSS/P3HT, as seen in the EE measurements. However, this work helps the developers understand the electronic interactions between the polymers, thus optimizing the photovoltaic devices since the GO in the buffer layer influenced the photophysics of the samples.

Effect of hysteresis on electrical properties in hybrid perovskite

e-mail: higor@fisica.ufmt.br

The use of Perovskites for the development of solar cells proves to be a good option due to the large absorption gap and has conversion efficiency approaching 25%. Lead triiodide methylammonium halide (MAPI) is a hybrid perovskite often applied in photovoltaic devices due to the low cost of reagents and fast manufacture. We noticed that hysteresis is frequent in perovskite, and it is a problem to get the actual efficiency of perovskite. We built a capacitor-like device, where the perovskite is in direct contact with the metallic layer. The perovskite has a manipulated deposition region, allowing more control of the device and enabling similar reproductions, using the two-step spin coating method. To speculate on the origin of hysteresis, we first understand if it originates from the transport layers, from the perovskite or even from the interface contacts [1], the effect of passivation changes the transient time scale of capacitive current. We used Scanning Electron Microscopy (SEM) and Atomic Force Microscopy (AFM) to analyze layer thicknesses. Using the four-point probe measurement technique, a forward and backward J-V sweep was performed, trying to identify the hysteresis behavior. We seek to understand if the origin of hysteresis occurs due to a possible ion migration, velocity of transient capacitive current or other factors [2] to develop solutions for the hysteresis and for further progress to improve the efficiency of devices. The hybrid perovskite CH3NH3PbI3 shows a capacitive effect in the J-V measurement, which implies an intrinsic ferroelectric behavior like the classical ceramic perovskite. We use theoretical models to realize computer simulations and complement the understanding of electronic carrier transport.

e-mail: jessica.rossato@unesp.br

The perovskite active layer (PVK) plays a critical role in the performance and the stability of perovskite solar cells (PSCs). An alternative to improve the performance of the PSCs, the incorporation of additives in the PVK layer during the preparation of the precursor's solution has drawn attention [1]. Recently, two-dimensional transition-metal dichalcogenides (TMDs), such as MoS_2, $MoSe_2$and $MoTe_2$, have been explored in the different layers of PSCs due to their admirable photostability, quantum efficiency and tunable band gap [2]. In this context, we explore the impact of MoS_2 -doped $Cs_{0.17}FA_{0.83}Pb(I_{0.83}Br_{0.17})_3$active layers in inverted PSCs. The incorporation of MoS_2into the PVK was confirmed by XDR patterns. Moreover, the XRD patterns showed an increase of crystallinity and a suppression of PbI_2formation with the increase of MoS_2content. High performance devices were obtained by the MoS_2-doped the active perovskite layer. The addition of the MoS_2resulted in a considerable increase of J_{sc}, $V_{oc}$and FF. The improvement of these parameters contributed to a substantial increase of PCE (22.4%) when compared to pristine active layer (19.24%) based devices. Photo-CELIV characterization showed improved charge mobility and higher density of extracted electrons of PSCs with the incorporation of MoS_2. An increase of charge recombination time with addition of MoS_2were shown in transient photovoltage measurements. In addition, the EIS measurements showed a decrease of the charge transfer resistance and an enhanced charge recombination resistance with addition of MoS_2.

e-mail: tatianemanke@hotmail.com

The reduce pollution and harmful gas emissions in the atmosphere, implementation of solar panels is one of the solutions, currently being one of the most exploited renewable energy sources and with excellent results. In the search for photoabsorbent materials with high performance and lower production costs, the route via microwave-assisted hydrothermal (MAH) has been used [1]. A blocking layer and the photoactive material of the solar cell characterize it as third-generation associated with hybrid-type perovskite. The main objective of this work is to explore materials synthed by the MAH method to improve photoabsorption when applied in solar cells. The initial tests are being carried out with the variation of the photoabsorber material: TiO_2, $KNbO_3$ and CaF_2 doped with rare earth ions. The deposition of the material was carried out using the spin-coating technique, by which some deposition parameters were varied, such as rotation and number of layers. Through the *JXV* curve, the partial results obtained show that $KNbO_3$ is a promising material for the blocking layer and can replace the usual TiO_2. Among all the cells made, the materials that have *Eu* and *Dy* ions had the best photocurrent results, attributed to the increase in the absorption band associated with the characteristic transitions of the dopant. Optical and morphological characterizations were also performed to investigate the influence of the deposition parameters used to assemble the solar cells.

Brazil stands out for having a predominantly renewable electrical matrix. In 2023, photovoltaic energy became the second largest source of renewable energy in Brazil, indicating a growth of 84% in less than a year. In this study, graphene oxide will be introduced to the ZnO/ZnS compound to form the photoelectrode of the dye-sensitized solar cell, aiming to reduce the electronic mobility problem of ZnO [1]. Moreover, it is expected that the graphene will enhance the anchorage of ZnS particles on ZnO, providing a better solar absorption. In this context, the purpose of this study is to understand how the insertion of graphene in different amounts in the ZnO/ZnS compound affect the system, evaluating the influence on the power conversion efficiency. To realize the production of solar cells, initially the ZnO/ZnS + GO will be synthed using the microwave-assisted hydrothermal method, which offers a shorter synthesis time and greater homogeneity. To the ZnO synthesis, sodium hydroxide and zinc acetate will be used as precursors, for the ZnS coating, will be used zinc chloride and thioacetamide because they presented better results in studies performed by our research group [2]. The insertion of graphene into the system will happen at the time of ZnS coating, to evaluate how it will influence the system under the presence of electromagnetic waves. Subsequently, a dye-sensitized solar cell will be assembled, where the photoelectrode will be a film formed by ZnO/ZnS+GO. To evaluate the results, x-ray diffraction will be performed to verify the crystalline phase, Scanning Electron Microscopy to verify the and distribution of the crystals, and photovoltaics measurements to obtain the power conversion efficiency.

Solar photovoltaic technology is an important contributor to the reduction of greenhouse gas emissions,[1]and the module efficiency of silicon solar cells is gradually increasing, getting closer and closer to the Shockley-Queisser limit.[2]In addition, efforts are being made to reduce the cost of electricity, and this can be achieved with technological advances in the efficiency of solar cells.[3]To achieve a lower cost per installed capacity, several pathways have been considered, with the objective of achieving a better use of the total energy of thesolar spectrum. In recent years, researchers have been working to optimize each componentof quantum dot-sensitized solar cells (QDSSC). One of the components to be optimized is the electrolyte, which has the function of regenerating the electrons on the surface of the counter electrode and the holes present in the active layer. Therefore, the ideal electrolyte should have the following characteristics: low redox potential, high diffusion coefficient and high electrical conductivity, thus promoting a fast regeneration of the quantum dots and an efficient transport between the electrodes. One strategy to increase electrolyte efficiency is to add additives. In this work, Cu-Zn-In-S/ZnS quantum dots were added to the polysulfide electrolyte in a $CuInS_2$ solar cell. From the results obtained, it was observed that the incorporation of the quantum dots in the electrolyte caused an increase in the efficiency of the solar cell compared to the standard electrolyte.

Organic Solar Cells (OSCs) have shown a marked increase in efficiency during the last decade due to the development of non-fullerene electron acceptors. However, for a given choice of donor and acceptor molecules, the optimization of these devices includes post-deposition treatments like solvent vapor annealing and thermal annealing, which can significantly improve the device' s performance. In this work, solar cells with active layers based on PTB7-Th as donor and CPDT-4F as acceptor were produced, and post-deposition treatments as solvent vapor annealing with chloroform (CF) and tetrahydrofuran (THF) and thermal annealing were performed on the active layers. To analyze the impact of these treatments on the morphology, SEM and AFM images were obtained, and both techniques showed significant changes in the morphology when solvent vapor annealing with CF and THF and thermal annealing were applied on the blends of PTB7-Th:CPDT-4F, both separately and consecutively. These post-treatments led to significant changes in the performance of the solar cells with the structure (ITO/PEDOT:PSS/PTB7-Th:CPDT-4F/PFN-Br/Al), with an increase of the Jsc, FF and Voc of the solar cells, which can be directly attributed to the changes in morphology observed by AFM and SEM. These results point to the importance of these post-deposition treatments to further optimize the active layer morphology, and consequently the solar cell efficiency.

e-mail: m.lemes@ufabc.edu.br

Hybrid organic-inorganic perovskite (HOIPs) represents a new class of materials with outstanding physical properties. These 2D materials possess a hydrophobic layer composed of organic spacer cations that offer resistance to heat and moisture. By virtue of their structural and electronic properties, organic spacers are crucial for engineering 2D perovskites, since they can act as a quantum well and also modulate the stability and optoelectronic efficiency. Nonetheless, systematic investigation on the structural and electronic roles is still limited and has not been extensively studied. With that in mind, we have carefully selected two structural isomers n-butylamine (BA) and isobutylamine (iBA) as cation spacers to synthesize 2D halide HOIPs. Such organic spacers are primary amines that satisfy the condition to create van der Waals interface within inorganic layers to achieve the desired 2D perovskite framework. Interestingly, the inductive electronic effect in iBA is an additive to better stabilize a proton, thereby ensuring effective non-covalent interactions through H-bonds. Thus,we have synthesized 2D HOIPs, via solvothermal method, aiming the stoichiometry $BA_2MAPb_2Cl_7$(1) and $iBA_2MAPb_2Cl_7$(2). The XRD patterns exhibit coexistence of Bragg's plane reflections at low angle that suggest contribution of different crystalline phase for (1) and (2). The observation of (200) and (400) planes confirms the growth of an orthorhombic crystal phase associated with the presence of two octahedral sheets building blocks of $[PbCl_6]^{4-}$(n = 2). Extra Bragg's reflections at low angle disclose the presence of a secondary and minority crystal phase (002) without MA molecules. Scanning electron microscopy images analysis show square-like microplates for (1) with the of ~ 20 μm, while rhombus-like planes of 50 μm are observed for (2). The ongoing charge transport and photoluminescent results will be rationalized and discussed considering the influence of organic spacer configuration.

Life Cycle Analysis of Solar Photovoltaic Energy Generation Materials: case study in the floating solar photovoltaic plant at the Santa Clara, Paraná Hydroelectric Powerplant

ASTOLFO JAVIER NARVAEZ BOTERO[1], Emerson Luís Alberti[2,3,4], Kleber Franke Portella[5], Mariana D' Orey Gaivão Portella Bragança[5], Mauricio Marlon Mazur[6], Viviane Teleginski Mazur[7]

In the last decade, the consumption and the installed capacity of photovoltaic generated electricity have reached a high rate of growth. The significant increase in energy conversion efficiency of solar panels and the relative decrease in equipment and system installation costs, both for industrial and residential customers, contributed to this growth. At the same time, it encouraged the search for alternatives to minimize the use of productive areas or areas distant from transmission lines. Consequently, hybrid generation systems were developed taking advantage of hydroelectric powerplant dams, given the advantage of already having the distribution infrastructure in addition to increasing the energy production efficiency of the panel due to the environment water cooling effect. Although considered as a clean form of energy generation, the analysis of its operation must be carried out (from cradle to grave) adopting the concept of cyclical economy, assessing the environmental impact of all stages of the system's useful life. In this investigation, a life cycle analysis (LCA) study was carried out, considering the impact caused by all components of a floating solar photovoltaic powerplant located in the Santa Clara hydroelectric plant dam, located on the Jordão River, between the cities of Candói and Pinhão, in the state of Paraná, Brazil (FloatPV SC), from its manufacturing, assembly, commissioning, use, disposal and/or recycling of components. The objective was to assess the real environmental impact caused, using the SimaPro® software tools, with updated inventory libraries and interfaces, where the segmentation of the plant components was considered, which are: the solar panels, the support structure, the floats, mooring systems, and inverters. In the research, the recommendations in the NBR ISO 14044 (Requirements and Guidelines) and 14040 (Principles and Structure) standards were used.

Mechanisms of Luminescence in RE-doped BaZrO3

Investigations of BaZrO3 Perovskite compounds suggest that the band-gap and its trappings are largely responsible for luminescence emissions, and their shape can be controlled by the conditions of synthesis of nanocrystals by the Microwave-Assisted Hydrothermal Method (MAH) [1-2]. Crystals doped with rare earths have received considerable attention due to the allowed 5d-4f transition, such as trivalent cerium (Ce3+) with good light yield and energy resolution achieved in many materials, having intrinsic phenomena such as luminescence or fluorescence by conversion energy [3]. This work aims to investigate the properties of BZO Perovskite polycrystals doped with rare earth, synthed using the HAM method, in order to understand their luminescence mechanisms resulting from the energy conversion process. BaZrO3 samples were synthed by the MAH method and characterized using XRD and SEM. XRD results indicated the majority crystalline phase of BaZrO3 with a cubic lattice. SEM images show the present shape and regular from undoped samples. BaZrO3 samples will be synthed and doped with RE, to the purpose of allowing the identification of changes in electronic structures, the influence on the synthesis process, establishing correlations with their optical properties, investigating energy conversion processes compared to pure BaZrO3 and to study potential applications in thin films for solar cells, to be analyzed through of photoluminescence, fluorescence, X-ray absorption and others measurements.

OBTAINING P3HT NANOFIBERS WITH PCBM FOR ACTIVE LAYERIN BULK HETEROJUNCTION SOLAR CELLS

Yngrid Synara de Sena Silva[1], Maria de Fátima Vieira Marques[2], Rayssa Pereira da Conceição Laino[1]

[1]Universidade Federal do Rio de Janeiro (*IMA*) , [2]Universidade Federal do Rio de Janeiro

e-mail: yngridsynara@gmail.com

Today, there is a need to increase the photovoltaic parameters (such as efficiency and fill factor) of bulk heterojunction organic solar cells (OPV) and to increase the thickness of the active layer without negatively affecting exciton recombination. One of the alternatives is to place nanofibers of the electron donor polymer and the acceptor material inside the active layer. The objective of this work is to obtain nanofibers containing poly(3-hexylthiophene) (P3HT) and [6,6]-phenyl C61-butyric acid methyl ester (PC61BM) from coaxial electrospinning. These nanofibers will be used as a component of the active layer in BHJ-type solar cells. The polymer used as a shell layer is polycaprolactone (PCL), and the core layer is P3HT with PCBM. The parameters studied in the electrospinning process were the pump''s flow rate used in core-shell-layer solutions and the distance between the needle and collector. The flow rate of the core layer solution had values of 0.1 ml/h, 0.2 ml/h, and 0.3 ml/h. The values of 0.5 ml/h and 1.0 ml/h were employed for the shell layer solution. The applied voltage was 15 KV. The shell layer was removed by immersing the nanofibers in acetone for 24 h. After this, the samples were dried in an oven at 70°C to eliminate all traces of the solvent. The quality of the nanofibers was analyzed by scanning electron microscopy (SEM) and transmission electron microscopy (TEM) in the presence and absence of the shell layer. In addition, FTIR spectroscopy of the nanofibers was performedto verify the complete absence of the shell layer.

Solar cells based on lead halide perovskites as an absorber material have shown high efficiency values of around 25%[1]. However, a major disadvantage of this material is its degradation over time, which considerably reduces the useful life of devices. One way to overcome this problem is by inserting organic cations and inorganic ions to increase the stability of the material [2]. In this work, we deposited the hybrid perovskite FA0.83Cs0.17Pb(Br0.17I0.83)3 and investigated its stability through optical measurements over time. One advantage of using optical characterizations for material investigation is the possibility of obtaining interface information without damaging the sample [3].

The perovskite was deposited on FTO (TEC7) using chemical route and spin-coating. Transmittance and reflectance measurements (specular and diffuse) were made for light falling on both sides of the samples. For the pristine deposited samples the maximum light scattering were 8%, which occurs preferentially in the perovskite grain boundaries. The Urbach energy obtained was in the order of 17-18 meV, indicating low disorder. Measurements over time showed a 35% drop in absorbance after 21 days, while the classic perovskite CH3NH3PbI3 (MAPbI3) deposited for comparison reached similar values in the first 72 hours, indicating greater stability of perovskite FA0.83Cs0.17Pb(Br0.17I0.83)3. The bandgap remained practically constant at 1.65 eV. The Urbach energy increased, reaching a value of 20-21 meV, associated with an increase in the disorder at the grain boundary, indicating a preferential degradation in this region.

e-mail: ymariza@usp.br

Organic solar cells (OSCs) are devices that convert light energy into electric current using small molecules or conjugated polymers [1]. Despite their high efficiencies, there is a lack of studies on the degradation of OSCs under continuous use and ambient conditions. In 2011, testing guidelines and protocols were established during the International Summer on Organic Photovoltaic Stability (ISOS) to standardize OSC reliability/stability tests [2]. However, many in the OSC community still do not follow these protocols, making it difficult to compare and replicate degradation data. This work focuses on studying degradation phenomena in OSCs under continuous operation following ISOS protocols, using a P3HT:PC61BM polymer blend in a conventional BHJ structure, J-V measurements were obtained under illumination, and degradation was measured using two ISOS protocols: ISOS-D1 and ISOS-L1. Results showed that the device retained 80% of its power conversion efficiency (PCE) after 3.5 hours (T80) for ISOS-D and after 0.5 hours (T80) for ISOS-L, with oxygen identified as a key factor in degradation. The guidelines for improving the lifetime of OSCs under continuous operation are discussed.
